TURPENTINE consists of the oleo-resins which exude from certain trees, especially from some conifers and from the terebinth tree, *Pistacia Terebinthus*, L. It was to the product of the latter, now known as Chian turpentine, that the term was first applied. The terebinth tree (*τέρμινθος* of Theophrastus) and its resin (*ρήτίνη τερμίνθων*) were well known and highly prized from the earliest times. The tree is a native of the islands and shores of the Mediterranean, passing eastward into Central Asia; but the resinous exudation found in commerce is collected in the island of Scio. Chian turpentine is a tenacious semi-fluid transparent body, yellow to dull brown in colour, with an agreeable resinous odour and little taste. On exposure to the air it becomes dry, hard, and brittle. In their general characters, turpentines are soft solids or semi-fluid bodies, consisting of a mixture of one or more resins with essential oils, which, although differing in physical properties, have a composition corresponding to the formula $C_{10}H_{16}$. They also contain minute quantities of oxygenated oils. Formerly they had considerable reputation in medicine, and they still continue to be employed in plasters and ointments; but their great use is in the arts, for which they are separated by distillation into rosin or colophony (see ROSIN, vol. xx. p. 852) and oil or spirit of turpentine.

Crude or common turpentine is the commercial name which embraces the oleo-resin yielded by several coniferous trees, both European and American. The principal European product, sometimes distinguished as Bordeaux turpentine, is obtained from the sea pine, *Pinus maritima*, in the Landes department of France. Crude turpentine is further yielded by the Scotch fir, *P. sylvestris*, throughout northern Europe, and by the Corsican pine, *P. Laricio*, in Austria and Corsica. In the United States the turpentine-yielding pines are the swamp pine, *P. palustris*, and the loblolly, *P. Tæda*, both inhabiting North and South Carolina, Georgia, and Alabama. Venice turpentine is yielded by the larch tree, *Larix europæa*, from which it is collected principally in Tyrol. Strasbourg turpentine is obtained from the bark of the silver fir; but it is collected only in small quantities. Less known turpentines are obtained from the mountain pine, *P. Pumilio*, the stone pine, *P. Cembra*, the Aleppo pine, *P. halepensis*, &c. The so-called Canadian balsam, from *Abies balsamea* (see BALSAM, vol. iii. p. 293), is also a true turpentine.

Oil of turpentine as a commercial product is obtained from all or any of these oleo-resins, but on a large scale only from crude or common turpentine. The essential oil is rectified by redistillation with water and alkaline carbonates, and the water which the oil carries over with it is removed by a further distillation over calcium chloride. Oil of turpentine is a colourless liquid of oily consistence, with a strong characteristic odour and a hot disagreeable taste. Its boiling point ranges from 152° to 172° C. at ordinary temperature; its sp. gr. is between 0.856 and 0.870; and in optical properties it rotates the plane of polarized light both to right and left in varying degrees according to its sources. It is soluble in alcohol, ether, benzol, other essential oils, and the fixed oils, and itself is a solvent of resins and caoutchouc. On exposure to the air it dries to a solid resin, and when oxidized in the presence of water gives off peroxide of hydrogen—a reaction utilized in the preparation of a disinfectant called “sanitas.” Oil of turpentine is largely used in the preparation of varnishes, and as a medium by painters in their “flat” colours.

¹ There is little external difference between the sexes, and the brightly-contrasted colours of the hen-bird seem to require some kind of concealment.

TURPIN, archbishop of Rheims and the supposititious author of *Historia Karoli Magni et Rotholandi*, is probably to be identified with Tilpin, who was archbishop of Rheims towards the end of the 8th century. This Tilpin is alluded to by Hincmar (845-882), his third successor in the see. According to Flodoard (ob. 969), Charles Martel drove Ragobert, bishop of Rheims, from his office, putting in his place a warrior-clerk, Milo. The same writer represents Milo as discharging a mission among the Vascones or Basques, the very people to whom authentic history has ascribed the great Carolingian disaster at Roncevaux. It is possible that we owe the warlike legends that have accumulated round the name of Turpin to some confusion of his identity with that of his martial predecessor. Flodoard says that Tilpin was originally a monk of St Denis; and we know from Hincmar that, after his appointment to Rheims, he occupied himself in securing the restoration of the metropolitan rights and landed property of his church, whose revenue and prestige had been impaired under Milo's rule. He was, according to the latter authority, elected in the days of Pippin, the son of Charles Martel, i.e., between 752 and 768. He died, if we may trust the evidence of a diploma alluded to by Mabillon, in 794. Hincmar, who composed his epitaph, makes him bishop for forty years and more, from which it is evident that he was elected somewhere about 754. Flodoard, however, states that he died in the forty-seventh year of his bishopric. Tilpin was present at the synod of Rome in 769; and Pope Hadrian, at the request of Charlemagne, sent him a pallium and confirmed the rights of his church (*Gallia Christiana*, ix. 28-30). According to Flodoard, he substituted monks for canons in the monastery of St Remigius; and 17th-century tradition ascribed to him an ancient *pontificale*, still extant in Marlot's days (17th century).

The above is a summary of all that authentic history and trustworthy tradition teach about the author to whom the common voice of the Middle Ages ascribed the *Historia Karoli Magni*. A short account of the work has been given elsewhere (ROLAND, LEGEND OF). But, popular as this production was during the Middle Ages, it was rather the crystallization of earlier Roland legends than the source of later ones. Potthast has enumerated about fifty codices without by any means, according to M. Gaston Paris, exhausting the list. The latter writer has made the *Historia Karoli* the subject of a special study (*De Pseudo-Turpino*, Paris, 1865), which may be recommended as a model of brilliant though cautious scholarship. The great popularity of the pseudo-Turpin seems to date from the latter half of the 12th century; and M. Paris enumerates at least five French translations belonging to the 13th, and one into Latin verse of about the same age. Mr Ward (*Cat. of Romances*, 549) has recently expressed a doubt as to whether the Turpin chronicle was completed at Vienne.

TURQUOISE, a blue or bluish green mineral, valued, when cut and polished, as an ornamental stone. The finest variety occurs in Persia, whence it originally reached western Europe by way of Turkey, and thus came to be called by the Venetians, who imported it, *turchesa*, and by the French *turquoise*. It is chemically a hydrated phosphate of aluminium, associated with a variable proportion of hydrated phosphate of copper, to which it owes much of its colour. The green tints of certain varieties appear to be due to admixture with salts of iron. A fine blue Persian turquoise, analysed by Prof. A. H. Church, yielded—alumina 40.19, phosphorus pentoxide 32.86, water 19.34, cupric oxide 5.27, ferrous oxide 2.21, and manganous oxide 0.36. The most valued tint of the turquoise is a delicate blue, inclining slightly to green; in many specimens the green becomes more pronounced with age. Although the turquoise is practically opaque, sections may be ground so thin as to admit of examination by transmitted light. Its microscopic structure was first studied by Prof. Fischer of Freiburg (Baden), afterwards by H. Bücking of Strasburg, and recently by Clarke and Diller.

Thin sections are almost colourless. Between crossed Nicols they show either a fibrous texture or a finely-granular aggregate of doubly-refracting particles without definite crystalline outlines. The mineral has never been found crystallized, but occurs as veins, nodules, stalactitic masses, and incrustations. Large pieces are exceedingly rare. The specific gravity of turquoise is about 2.75, and its hardness below 6; it takes a fair polish and exhibits a feeble lustre. It is usually cut *en cabochon* or with a low convex surface, and in the East is frequently engraved with Persian and Arabic inscriptions, generally passages from the Koran,—the incised characters being in many cases gilt. Such objects are worn as amulets. The turquoise has always been associated with curious superstitions, the most common being the notion that it changes colour with variations in the state of its owner's health, or even in sympathy with his affections.

Persia is the chief centre of the turquoise trade, where the same mines have been worked for at least eight centuries. The finest stones are found near Nishápúr in Khorásan (see PERSIA, vol. xviii. p. 622). Tavernier, writing in the 17th century, states that the best turquoise, reserved for the sole use of the shah, was obtained from the mine which he describes as the *Vieille Roche*, while inferior stones were got from the *Nouvelle Roche*. These terms still survive, all turquoise of fine colour being said in trade to be from the "old rock," and that which is pale, or changes tint on exposure, is from the "new rock." According to a recent report by Consul Benjamin at Teheran the best turquoise is found at Abú Riáh, and all the Khorásan mines are farmed by a few prominent officials, who pay to the shah an annual rent of about £6500. Dr Tietze has lately described specimens of the matrix of the mineral brought to Vienna from Persia by General Schindler. These show that the turquoise occurs, not in clay-slate, as is often stated, but in a porphyritic trachyte or trachytic breccia, and in loose fragments in the neighbouring alluvium. The mineral is also found in Kerman in southern Persia, but the stone is of pale colour, tending to fade, and the mines which yield it are now nearly abandoned. In 1849 Major C. Macdonald found turquoise in Wady Maghara and Wady Sidreh, near SINAI (*g.v.*), where, according to Mr H. Baerman, it lines the open joints of a ferruginous sandstone, and is also embedded in small ochreous nodules in the rock itself. The redder the rock the finer the colour of the associated turquoise. As the colour is liable to fade, the Arabian turquoise has not a good name among jewellers, and the workings were abandoned by Macdonald in 1865. In Wady Maghara there are relics of extensive mining operations, presumably for turquoise, of so early a date that the rock was wrought by flint implements. The early inhabitants of Mexico made much use of this mineral for inlaying obsidian ornaments, and for mosaic work with iron-pyrites. It was probably one of the stones known as *chilchihuitl*. In 1858 Prof. W. P. Blake called attention to the occurrence of turquoise at Cerillos, about 22 miles south-west of Santa Fé, in New Mexico, where mining operations for this mineral were carried on two centuries ago. The turquoise varies in colour from sky-blue to apple-green, and is found as nodules and small veins in a felspathic rock of microgranitic texture, probably of eruptive origin. The mines of Cerillos are no longer worked. A similar green mineral is found at Turquoise Mountain in Cochise county and at Mineral Park, Mohave county, Arizona. It also occurs to a small extent in southern Nevada, where it is found as blue grains disseminated through a sandstone. In Europe, the turquoise is found at Oelsnitz in Saxony and near Jordansmühl in Silesia, occurring at the latter locality in clay-slate. Under the names of *callais* and *callaina* Pliny described a green mineral which, if not our turquoise, seems to have been very closely related to it. A bright green mineral, wrought into beads, and found with stone hatchets in ancient graves at Men-er Hroek (Rock of the Fairy) in Brittany, was described in 1864 by M. Damour, who, seeking to identify it with Pliny's *callais*, revived this name. Dana afterwards brought the word into harmony with our mineralogical nomenclature by writing it *callainite*. The mineral in question is a hydrated phosphate of aluminium, apparently identical with Breithaupt's variscite. By many mineralogists the true turquoise is called *calaité* (see vol. xvi. p. 405).

Turquoise is commonly imitated by enamels, but of late some ingenious counterfeits have been made with the same chemical composition as the natural stone. To increase the deception, pieces of ochreous matter are inserted at the back of the artificial turquoise, to imitate the natural matrix. In order to distinguish between the genuine stone and its imitations, Pohl recommends that a splinter should be strongly heated in a platinum capsule, when the true turquoise is reduced to a brownish black powder or a friable mass with a decrepitating sound; the false turquoise does not decrepitate, but either fuses to a glass or is reduced to a frit.

For recent information on the turquoise, see "Das Vorkommen der Türkise bei Nischapur in Persien," by Dr E. Tietze, in *Verhandl. d. k. k. geolog. Reichsanstalt*, No. 6, 1884, p. 93; "Mikroskopische Untersuchung des Türkis," by H. Bücking, in *Zeitsch. f. Krystallog.*, vol. ii., 1878, p. 163; "Eine einfache und sichere Unterscheidungsweise der echten Türkise von deren Nachahmungen," in *N. Jahrb. f. Mineralogie*, 1878, p. 864; "Turquois from New Mexico," by F. W. Clarke and J. S. Diller, in *Americ. Journ. Science*, Sept. 1886, p. 211; "Revision of Mineral Phosphates, No. iv., Calaité," by A. H. Church, in *Chem. News*, x. p. 290; and note in *Journ. Soc. Arts*, xxxii., 1884, p. 1084.

TURRETIN, or TURRETINI. Three theologians of this name figure in the history of Genevan theology.

1. **Benot Turretin** (1588-1631), the son of Francesco Turretini, a native of Lucca, who settled in Geneva in 1579, was born in that town on 9th November 1588. He was ordained a pastor in Geneva in 1612, and became professor of theology in 1618. In 1620 he represented the Genevan Church at the national synod of Alais, when the decrees of the synod of Dort were introduced into France; and in 1621 he was sent on a successful mission to the states general of Holland, and to the authorities of the Hanseatic towns, with reference to the defence of Geneva against the threatened attacks of the duke of Savoy. He published in 1618-20 a defence of the Genevan translation of the Bible. Benot Turretin died at Geneva on 4th March 1631.

2. **François Turretin** (1623-87), son of the preceding, was born at Geneva on 17th October 1623. After studying theology in Geneva, Holland, and France, he became a pastor in Geneva in 1647; after a brief pastorate at Leyden, he again returned to Geneva as professor of theology in 1653. He was one of the most influential supporters of the *Formula Consensus Helvetica*, drawn up chiefly by Heidegger, in 1675, and of the particular type of Calvinistic theology which that symbol embodied. His *Institutio Theologiæ Elencticæ* (3 vols. 4to, Geneva, 1680-83) has passed through frequent editions, the last reprint having been made in Edinburgh in 1847. F. Turretin died at Geneva on 28th September 1687. He was also the author of volumes entitled *De Satisfactione Christi Disputationes* (Geneva, 1666) and *De Necessaria Secessione Nostra ab Ecclesia Romana* (Geneva, 1687).

3. **Jean Alphonse Turretin** (1671-1737), son of the preceding, was born at Geneva on 13th August 1671. He was educated at Geneva and in Holland, and after travelling in England and in France was received into the "Vénérable Compagnie des Pasteurs" of Geneva in 1693. In 1697 he became professor of church history. During the next forty years of his life he enjoyed great influence in Geneva as the advocate of a more liberal theology than had prevailed under the preceding generation, and it was largely through his instrumentality that the use of the *Formula Consensus Helvetica* as a symbol was discontinued in 1725. He also wrote and laboured for the promotion of union between the Reformed and Lutheran Churches, his most important work in this connexion being *Nubes Testium pro Moderato et Pacifico de Rebus Theologicis Judicio, et Instituenda inter Protestantes Concordia* (Geneva, 1719). Besides this he wrote *Cogitationes et Dissertationes Theologiæ*, on the principles of natural and revealed religion (Geneva, 1737); and commentaries on Thessalonians and Romans were published posthumously. He died at Geneva on 1st May 1737.

TURTLE. See TORTOISE.

TUSCANY (Ital. *Toscana*), one of the sixteen compartments of the kingdom of Italy, contains eight provinces—Arezzo, Florence, Grosseto, Leghorn, Lucca, Massa-Carrara, Pisa, and Siena—and has an area of 9287 square miles, with a population of 2,208,869 in 1881. In 1859, immediately before it united with the kingdom of Sardinia, the grand-duchy of Tuscany, exclusive of Massa-Carrara, which then belonged to Modena, but including the islands of Gorgona, Elba, Pianosa, Formica, Montecristo, Giglio, and Gianutra, as well as the duchy of Lucca (united to it

in 1847), had an area of 8625 square miles and a population of 1,806,940. See ITALY, vol. xiii pp. 489-490.

ETRURIA (*q.v.*) was finally annexed to Rome in 351 B.C. (see ROME), and constituted the seventh of the eleven regions into which Italy was, for administrative purposes, divided by Augustus. Under Constantine it was united into one province with Umbria, an arrangement which subsisted until at least 400, as the *Notitia* speaks of a "consularis Tuscia et Umbria." In Ammianus Marcellinus there is implied a distinction between "Tuscia suburbicaria" and "Tuscia annonaria," the latter being that portion which lies to the north of the Arno. After the fall of the Western empire Tuscia, with other provinces of Italy, came successively under the sway of Herulians, Ostrogoths, and Greek and Lombard dukes. Under the last-named, "Tuscia Langobardorum," comprising the districts of Viterbo, Corneto, and Bolsena, was distinguished from "Tuscia Regni," which lay more to the north. Under Charlemagne the name of Tuscia or Toscana became restricted to the latter only. One of the earliest of the Frankish marquises was Boniface, either first or second of that name, who about 828 fought with success against the Saracens in Africa. Adalbert I., who succeeded him, in 878 espoused the cause of Carloman as against his brother Louis III. of France, and suffered excommunication and imprisonment in consequence. Adalbert II. (the Rich), who married the ambitious Bertha, daughter of Lothair, king of Lorraine, took a prominent part in the politics of his day. A subsequent marquis, Hugo (the Great), became also duke of Spoleto in 989. The male line of marquises ended with Boniface II. (or III.), who was murdered in 1052. His widow, Beatrice, in 1055 married Godfrey, duke of Lorraine, and governed the country till her death in 1076, when she was succeeded by MATILDA (*q.v.*), her only child by her first husband. Matilda died in 1114 without issue, bequeathing all her extensive possessions to the church. The consequent struggle between the popes, who claimed the inheritance, and the emperors, who maintained that the countess had no right to dispose of imperial fiefs, enabled the principal cities of Tuscany gradually to assert their independence and govern themselves under consuls and elders of their own selection. The most important of these Tuscan republics or self-governed communes were Florence, Pisa, Siena, Arezzo, Pistoia, and Lucca. Some account of the manner in which they were all gradually absorbed by Florence will be found under FLORENCE and MEDICI. The title of grand-duke of Tuscany was conferred on Cosmo de' Medici by Pius V. in 1567, and the emperor (Maximilian II.), after withholding his consent for some years, ultimately confirmed it to Cosmo's successor in 1576. In 1735, in view of the childlessness of Giovan Gastone, the last of the Medici, the succession of Francis, duke of Lorraine, afterwards emperor Francis I., was arranged for by treaty. In 1765 he was succeeded as grand-duke by his second son Leopold (see LEOPOLD II.), who, on becoming emperor in 1790, handed Tuscany over to his second son Ferdinand, third grand-duke of the name. The duchy was occupied by the French in 1799, ceded to Louis, prince of Parma, by the convention of Madrid in 1801, and annexed to the French empire in 1808. Ferdinand, however, was reinstated in 1814, and on his death in 1824 was succeeded by his son Leopold, second grand-duke of the name, who was deposed by the constituent assembly on 16th August 1860. See ITALY.

TUSCULUM, an ancient Latin city, situated in a commanding position on one of the eastern ridges of the Alban Hills, near the site of the modern FRASCATI (*q.v.*). It has a very beautiful and extensive view of the Campagna, with Rome lying fifteen miles¹ distant to the north-west, on the west the sea near Ostia, and the long range of the Sabine Hills on the north-east. According to tradition, the city was founded by Telegonus, the son of Ulysses and Circe; hence Horace (*Epod.*, i. 30) speaks of it as "Circæa mœnia" and Ovid (*Fast.*, iii. 91) as "Telegoni mœnia" (see also Prop., iii. 30; 4, and Sil. Ital., xii. 535). The legendary descent of one of the chief Tusculan families, the gens Mamiliæ, from Ulysses through Telegonus is commemorated on some denarii struck by the Mamilian gens in the later years of the Roman republic; these have on the reverse a figure of Ulysses recognized by his dog Argo. When Tarquinius Superbus was expelled from Rome his cause was espoused by the chief of Tusculum, Octavius Mamilius, who took a leading part in the formation of the Latin League, composed of the thirty principal cities of Latium, banded together against Rome. Mamilius commanded the Latin army at the battle of Lake Regillus, a

piece of water which then lay immediately below the Colles Tusculani, but is now dried up. At this battle (497 B.C.) Mamilius was killed, and the predominance of Rome among the Latin cities was practically established. From that time Tusculum became an ally of Rome, and on that account frequently incurred the hostility of the other Latin cities. In 378 B.C., after an expression of complete submission to Rome, the people of Tusculum received the Roman franchise, and thenceforth the city continued to hold the rank of a *municipium*. Several of the chief Roman families were of Tusculan origin, *e.g.*, the gentes Mamilia, Fulvia, Fonteia, Juventia, and Porcia; to the last-named the celebrated Catos belonged. During the imperial period little is recorded about Tusculum; but soon after the transference of the seat of empire to Constantinople it became a very important stronghold, and for some centuries its counts occupied a leading position in Rome and were specially influential in the selection of the popes. During the 12th century there were constant struggles between Rome and Tusculum, and towards the close of the century the Romans, supported by the German emperor, gained the upper hand, and the walls of Tusculum, together with the greater part of the city, were destroyed.

Extensive remains still exist of the massive walls, which surrounded the city, and of its *arx*—a separate citadel—which stood on an abrupt rock, approached only on one side, that towards the city, with which it was connected by long walls. The walls are built of large blocks of the native "lapis Albanus" or peperino, some of them as much as 5 feet long by 3 feet thick. They probably belong to the early republican period; restorations in concrete faced with "opus reticulatum" of the 1st century B.C. can be traced in many places.

During the latter years of the republic and under the empire Tusculum was a favourite site for the country villas of wealthy Romans. That of Lucullus was very large and magnificent; other handsome houses were built there by Julius Cæsar, L. Crassus, Q. Metellus, Marcus Brutus, and others. A palace was erected by Tiberius near Tusculum on the way to Rome, close to the Via Latina.

The most interesting associations of the city are those connected with Cicero, whose favourite residence and retreat for study and literary work was at Tusculum. It was here that he composed his celebrated *Tusculan Disputations* and other philosophical works. Much has been written on the position of his villa, but its true site still remains doubtful. Its grounds are known to have adjoined the more splendid villas of Lucullus and the consul Gabinius (see Cic., *De Fin.*, iii. 2, and *Pro Dom.*, 24). The most probable site is that now marked by the Villa Rufinella to the west of Tusculum, where the hill is divided into two ridges. The scholiast on Horace, *Epod.*, i. 30, states that Cicero's villa was "ad latera superiora," the plural probably being used in allusion to the double ridge. The other theory, which places the site at Grotta Ferrata, some distance farther to the west, has little evidence to support it. Although Cicero (*Pro Sestio*, 43) speaks of his own house as being insignificant in size compared to that of his neighbour Gabinius, yet we gather from other notices in various parts of his works that it was a building of no mean size and pretension. It comprised two gymnasia (*Div.*, i. 5), with covered *porticus* for exercise and philosophical discussion (*Tusc. Disp.*, ii. 3). One of these, which stood on higher ground, was called "the Lyceum," and contained a library (*Div.*, ii. 3); the other, on a lower site, shaded by rows of trees, was called "the Academy." The main building contained a covered *porticus* or cloister, with apsidal recesses (*exedrae*) containing seats (see *Ad Fam.*, vii. 23). It also had bath-rooms (*Ad Fam.*, xiv. 20), and contained a number of works of art, both pictures and statues in bronze and marble (*Ep. ad Att.*, i. 1, 8, 9, 10). The central atrium appears to have been small, as Cicero speaks of it as an *atriolum* (*Ad Quint. Fr.*, iii. 1). The cost of this and the other house which he built at Pompeii led to his being burdened with debt (*Ep. ad Att.*, ii. 1). Nothing now exists which can be asserted to be part of Cicero's villa with any degree of certainty. The so-called "scuola di Cicerone," near the line of the ancient wall of Tusculum, is the substructure of some building formed in the usual Roman way by a series of vaulted chambers, and is clearly later in date than the time of Cicero. Other remains of houses exist in and near the city, but nothing is known as to their history or ownership.

Ruins of two theatres still exist. One of them, which is not earlier than the beginning of the 1st century, between the city and the *arx*, is fairly perfect, and still possesses most of its ancient seats, divided into four *cunei* by three flights of steps. Only traces remain

¹ Dionysius (x. 20) states that Tusculum was only 100 stadia (about 12½ miles) from Rome; but the fifteenth milestone on the Via Latina was close to the walls of Tusculum.

of the other theatre, which abutted against the long walls that defended the road from the city to the arx. Remains of an amphitheatre of no great size can be traced, dating probably from the 3d century. There is also a large *piscina*, near the first-mentioned theatre. In the vicinity of Tusculum a number of interesting tombs have been discovered at various times; some, as for example that of the Furii, contained valuable inscriptions of the 4th and 3d centuries B.C.

The city was supplied with water by the Aqua Crabra, and near it were the springs which fed two of the Roman aqueducts—the Aqua Tepula and Aqua Virgo (Front., *De Ag.*, 8).

For further information the reader is referred to Compagni, *Memorie Storiche dell' Antico Tuscolo*; Canina, *Descr. dell' Antico Tuscolo*; Gell, *Topogr. of Rome and its Vicinity*; and Nibby, *Dintorni di Roma*, vol. iii.

TUSSER, THOMAS (c. 1527-1580), poet, was the son of William Tusser by Isabella, daughter of Thomas Smith of Rivenhall, Essex, where he was born about 1527. Notwithstanding strong reluctance on his part he was sent in his early years to a music school, and became chorister in the collegiate chapel of the castle of Wallingford. He was afterwards admitted into the choir of St Paul's, and went thence to Eton, where he was under the tuition of Nicholas Udall. In 1543 he was elected to King's College, Cambridge, and soon afterwards exchanged to Trinity Hall. On leaving the university he was for about ten years at court, probably in some musical capacity. He then settled as a farmer in Suffolk, near the river Stour, an employment which he seems to have regarded as combining the chief essentials of human felicity. Subsequently he lived successively at Ipswich, West Dereham, Norwich, and London. There he died in April 1580, and was buried in the church of St Mildred in the Poultry. His monument was destroyed in the fire, but the quaint epitaph is preserved in Stow's *Survey of London*. A marble tablet, on which the epitaph is inscribed, has been erected to him in the church of Manningtree, Essex.

Tusser's poems on husbandry have the charm of simplicity and directness, and their practical saws were apparently relished, for in his lifetime they went through a number of editions. They are *A Hundreth Good Pointes of Husbandrie*, 1557, 1561, 1562, 1564, and 1570; *A Dialogue Wyngynge and Thryngynge*, 1567; *A Hundreth Good Pointes of Husbandrie lately married unto a Hundreth Good Pointes of Huswifery*, 1570; *Five Hundreth Pointes of Good Husbandrie united to as many of Good Wifery*, 1573, 1576, 1577, 1585, 1586, 1590, 1593, reprinted with memoir by William Mavor, 1812, by Auber, 1873, and by the English Dialect Society, 1879. His metrical autobiography, printed in the Appendix to *Five Hundreth Pointes*, 1578, was republished in 1846 along with his will, which would seem to refute the sarcasms which became current, that he had not been successful in practising his own maxims. One of these references is contained in a volume of epigrams by H. P., *The More the Merrier*, 1608. One of the epigrams entitled *Ad Tusserum*, begins thus:—

"Tusser, they tell me, when thou wert alive,
Thou, teaching thrift, thyself could'st never thrive."

Possibly Tusser obtained the reputation of being poor from his practice of thrift; but in any case, if his will represents his worldly condition at the time of his death, he was not in poverty in his later years.

TVER, a government of central Russia, on the upper Volga, bounded by Pskoff and Novgorod on the W. and N., Yaroslavl and Vladimir on the E., and Moscow and Smolensk on the S.; it has an area of 25,225 square miles. Lying on the southern slope of the Valdai plateau, and intersected by deep valleys, it has the aspect of a hilly region, but is in reality a plateau ranging from 800 to 1000 feet in height. Its highest parts are in the north-west, where the Volga, Western Dwina, and Msta rise in marshes and lakes. The plateau is chiefly built up of Carboniferous limestones, Lower and Upper, underlain by Devonian and Silurian deposits, which appear only in the denudations of the lower valleys. The whole is covered by a thick sheet of boulder-clay (the bottom-moraine of the Scandinauo-Russian ice-sheet) and subsequent lacustrine deposits. A number of *âsar* (see vol. x. p. 368) occur on the slopes of the plateau. Ochre, brick, and pottery clays, as also limestone for building, are obtained, and there are

chalybeate springs. The soil, which is clayey for the most part, is not fertile as a rule.

Nearly the whole of Tver is watered by the upper Volga (350 miles) and its tributaries, several of which (Yazuza, Dubna, Sestra, Tvertsa, and the tributaries of the Mologa) are navigable. The Vyshnevototsk system of canals connects the Volga (navigable some 60 miles from its source) with the Baltic, and the Tikhvin system connects the Mologa with Lake Ladoga. The Msta, which flows into Lake Ilmen, and its tributary the Tsna, water Tver in the north-west, and the Western Dwina rises in Ostashkoff. This network of rivers highly favours navigation: as many as 3000 boats yearly pass through the Vyshnevototsk system, and corn, linseed, spirits, flax, hemp, timber, metals, and manufactured ware to the annual value of £1,500,000 are shipped from, or brought to, the river ports of the government. Lakes, ponds, and marshes are numerous in the west and north-west, Lake Seliger—the source of the Volga—and Lake Mstino being the most important. The forests—coniferous in the north and deciduous in the south—are rapidly disappearing, but still cover 890,000 acres. The climate is continental; the average yearly temperature at Tver (41°·5 Fahr.) is the same as that of Orel and Tamboff (January 11°, July 67°). The population (1,646,683 in 1883, as against 1,567,300 in 1872) is unequally distributed, and in the districts of Kalyazin and Kashin attains a density not much less than that of the more highly favoured black-earth provinces of south-east Russia (16 and 17 per square mile). Apart from some 100,000 Karelians and a few Poles and foreigners, the people are all Great Russians. Some traces of Finnish Vses and of Lithuanians are found in the north-east and south. The official returns give the number of Raskolniks as 25,000. Only 157,110 are urban; but agriculture is not the chief occupation. While barley and oats are exported, rye is imported. The crops for 1883-1885 averaged 2,889,400 quarters of corn and 4,078,400 bushels of potatoes. Cattle-rearing does not prosper, and the increase shown by the returns for 1883 (351,630 horses, 583,670 cattle, and 373,780 sheep) as against those of 1872 is simply due to better registration. Cheese-making has recently been introduced on the co-operative principle (2168 cwts. of cheddar exported to Britain in 1881). The fisheries in the lakes and rivers are productive. The peasants are principally engaged in various manufactures. The total production of the larger manufactures in 1883 was valued at £2,237,250 (tanneries £244,460, cottons £803,270, distilleries £320,010, flour-mills £263,500), and that of the petty trades carried on in combination with agriculture (preparation of pitch, tar, and turpentine, boat-building, construction of cars, sledges, wheels, boxes, tubes, and wooden vessels, and cabinet-making) was estimated in 1884 at £3,000,000, giving occupation to 101,400 persons. Certain branches of the leather industry are important, Kimry and Ostashkoff sending to the market £650,000 worth of boots annually. The small workshops of Tver and the surrounding district work some 4500 cwts. of iron into nails every year, and the Ostashkoff smiths use some 7000 cwts. of iron annually in the manufacture of hatchets, scythes, sickles, and different agricultural implements. Weaving, lace-making, leather embroidery, stocking-making, felting, and the like are also important petty trades, several of these being organized on co-operative principles by the *zemstvos*. The railway from St Petersburg to Moscow crosses Tver, and sends off two branches to Rzheff and to Rybinsk, all three lines being among the busiest in Russia. The river traffic also is considerable. The chief centres of trade, besides the city of Tver, are Byezhetsk, Rzheff, Kashin, Ostashkoff, Torshok, Krasnyi Kholm, and Vesiegonsk during its fair. The provincial assembly of Tver is one of the most prominent in Russia for its efforts in the cause of education and sanitary improvement. In 1883 there were 997 primary schools with 47,680 scholars (8500 girls), 17 gymnasias and progymnasias (1697 boys and 1263 girls), and two normal schools for teachers. The government is divided into twelve districts, the chief towns of which, with their populations in 1884, are—TVER (see below), Byezhetsk (5890), Kalyazin (5200), Kashin (5780), Kortcheva (2275), Ostashkoff (9900), Rzheff (26,480), Staritsa (2700), Torshok (12,910), Vesiegonsk (3370), Vyshniy Vototshok (11,590), and Zubtsoff (3160).

TVER, capital of the above government, lies 102 miles by rail to the north-west of Moscow, on both banks of the Volga (here crossed by a floating bridge) at its junction with the Tvertsa. The low right bank is protected from inundations by a dam. As a whole the town is but poorly built. The oldest church dates from 1564, and the cathedral from 1689. An imperial palace, the courts, and the post-office rank among its best buildings. A public garden occupies the site of the former fortress. The population was 39,100 in 1884. The manufactures, chiefly of cotton, employ 5900 workmen (5710 at the cotton mills), and a number of nail-making workshops employ some 800 men, while more than 1000 women are engaged in the domestic

manufactory of hosiery for export to Moscow and St Petersburg. The traffic of the town is considerable, Tver being an intermediate place for the trade of both capitals with the provinces of the upper Volga.

Tver dates its origin from 1180, when a fort was erected at the mouth of the Tvertsa to protect the Suzdal principality against Novgorod. In the 13th century it became the capital of an independent principality, and remained so until the end of the 15th century. Mikhail Yaroslavovitch, prince of Tver, was killed fighting against the Tatars, as also was Alexander Mikhailovitch, who boldly fought for the independence of Tver against Moscow. It long remained an open question whether Moscow or Tver would ultimately gain the supremacy in Great Russia, and it was only with the help of the Tatars that the princes of the former eventually succeeded in breaking down the independence of Tver. In 1486, when the city was almost entirely burned down by the Muscovites, the son of Ivan III. became prince of Tver; the final annexation to Moscow followed four years later. In 1570 Tver had to endure, for some reason now difficult to understand, the vengeance of Ivan the Terrible, who ordered the massacre of 90,000 inhabitants of the principality. In 1609-12 it was plundered both by the followers of the second false Demetrius and by the Poles.

TWEED, a river in the south of Scotland, has its rise in the south-west corner of Peeblesshire, not far from the Devil's Beef Tub in Dumfriesshire. The stream flowing from Tweed's Well, about 1500 feet above sea-level, is generally regarded as its source, although the honour is also claimed for other streams issuing from a higher elevation. For the first 36 miles of its course it intersects the county of Peebles—frequently on this account called Tweeddale—in a north-easterly direction, passing between verdant hills separated by valleys watered by its numerous affluents. Having passed several picturesque keeps and castles, it reaches the town of Peebles, shortly before which it receives the Lyne Water from the north and the Manor Water from the south. The valley now widens; the scenery becomes softer and richer; and the river, bending in a more easterly direction, passes Innerleithen, where it receives the Leithen from the north and the Quair from the south. It then crosses Selkirkshire in a south-easterly direction, and, having received the Ettrick from the south on the borders of Roxburghshire, flows northward past Abbotsford, forming for about 2 miles the boundary between the counties of Selkirk and Roxburgh. After receiving the Gala, the Tweed crosses the north-western corner of Roxburghshire past Melrose and its abbey, and, after being joined by the Leader from the north, winds past Dryburgh abbey round the south-western corner of Berwickshire. The remainder of its course is in a north-easterly direction through Roxburghshire past Kelso, where it receives the Teviot from the south, and then between the counties of Berwick and Northumberland, past Coldstream and Norham castle to the town of Berwick, where it reaches the North Sea. It receives the Eden Water from the north at Edenmouth, the Leet Water from the north at Coldstream, and the Till from Northumberland between Coldstream and Norham castle. The last 2 miles of its course before reaching Berwick are in England. Though the latter part of its course is through a comparatively level country, the scenery along the river is full of charm, owing to the picturesque variety of its finely wooded banks. The associations connected with the keeps and castles of the Tweed have supplied materials for several of Sir Walter Scott's poems and romances; and its varied beauties have been sung by Hogg, Leyden, Thomson, and many others. The bed of the river is pebbly and sandy, and, notwithstanding discolorations from manufactures, the stream, from its clear and sparkling appearance, is still well entitled to the name of the "silver Tweed." The total area drained by it is about 1870 square miles, and its total length is 97 miles. Next to the Tay it is the largest river in Scotland. The Tweed has, however, no estuary, and its traffic is chiefly confined to Berwick. But for a short dis-

tance up the river some navigation is carried on by barges. The river is one of the best in Scotland for trout and salmon fishing.

See Sir Thomas Dick Lauder's *Scottish Rivers* and Prof. Veitch's *River Tweed*, 1884.

TWEEDS. See WOOLLEN AND WORSTED MANUFACTURES.

TWELVE TABLES. See ROMAN LAW, vol. xx. p. 679 sq., and ROME, vol. xx. p. 737.

TWENTY-FOUR PARGANAS, the metropolitan district of the lieutenant-governorship of Bengal, India, takes its name from the territory originally ceded to the East India Company, which contained twenty-four parganas or sub-districts. The district lies between 21° 55' 20" and 22° 57' 32" N. lat. and 88° 6' 45" and 88° 20' 51" E. long. It has an area of 2124 square miles, and is bounded on the north by Nadiyá, on the north-east by Jessore, on the south and south-east by the Sundarbans, and on the west by the river Húgli (Hooghly). The country consists for the most part of a vast alluvial plain within the delta of the Ganges, and is everywhere watered by numerous rivers, all branches of the Húgli. In the northern portion the soil is very rich, but the southern or seaboard part consists of the network of swamps and inland channels known as the Sundarbans. The Húgli and six other streams are navigable by the largest boats throughout the year. The district is well supplied with canals, the most important being Tolly's Nala (10 miles long), which connects the Húgli with the Bidyádhari. The Twenty-Four Parganas was once famous for its sport, but owing to the extension of cultivation game is now scarce. Tigers are seldom met with; leopards are more numerous; there are several varieties of deer. The district has many roads, and is traversed by the Eastern Bengal Railway and the Calcutta and South-Eastern State Railway.

In 1881 the population of the district, exclusive of Calcutta, numbered 1,869,859 (males 975,430, females 894,429), embracing 1,153,040 Hindus, 701,306 Mohammedans, and 13,976 Christians. The ten following municipalities had each a population of upwards of 10,000—South Suburban, 51,658; Agarpara, 30,317; Barangan, 29,982; Naihati, 21,533; Nawabganj, 17,702; Basurhat, 14,843; South Dum Dum, 14,108; Baduria, 12,981; Rajpore, 10,576; and Barasat, 10,533. The administrative headquarters of the district are at Alipur, a southern suburb of Calcutta. Rice forms the staple crop of the district; other crops are pulses, oil seeds, sugar-cane, tobacco, &c. Its principal exports are rice, sugar, *pan* leaf, fish, pottery, &c.; the imports comprise pulses of all kinds, oil-seeds, spices, turmeric, chillies, cloth, cotton, &c. The objects of the rural manufactures are sugar, cotton curtains, brass and iron work, horn sticks, and cotton and *tasar* silk cloth. The gross revenue of the district in 1885-86 amounted to £338,895, of which the land-tax contributed £155,181. The district was ceded to the East India Company by treaty by the nawáb nazim of Bengal in 1757. Since then several changes have been made in its boundaries, the latest in 1863.

TWICKENHAM, a town of Middlesex, England, is situated on the north bank of the Thames and on the London and South-Western Railway, 11½ miles south-west of London by rail. It is a straggling and irregular town, but has many fine suburban villas, and the district is noted for its sylvan beauty. Opposite the town there is an eyot in the river about 8 acres in extent, called Eel Pie Island, much resorted to by boating parties. The parish church of St Mary was rebuilt in red brick in very plain style after the fall of the old one in 1713, but the picturesque western tower of the 14th century still remains. It contains many interesting monuments, including one to Pope, who was buried in the nave. The principal public buildings are the town-hall and assembly rooms (built in 1876, and containing the free library established in 1882), the economic museum, the royal naval female school for the daughters of naval and marine officers, the Montpellier lecture hall, the metropolitan and City of London police orphanage, the almshouses of the London Carpenters' Com-

pany, and a branch of the national refuge for the homeless and destitute. The population of the urban sanitary district (area 2415 acres) in 1871 was 10,533, and in 1881 it was 12,479.

Twickenham at Domesday was included in Isleworth. Anciently it was called Twittenham or Twicanham. The manor was given in 941 by King Edmund to the monks of Christ Church, Canterbury, from whom it had been previously taken, but it was again alienated, for it was restored to the same monks by Edred in 948. In the reign of Henry VIII. it came into the possession of the crown, and by Charles I. was assigned to Henrietta Maria as part of her jointure. It was sold during the Protectorate, but after the Restoration the queen mother resumed possession of it. In 1670 it was settled for life on Catherine of Braganza, queen of Charles II. It still remains in possession of the crown, but since the death of Catherine has been let on leases. In the neighbourhood are many residences of literary or historical interest. Pope's villa, where he lived from 1717 till his death in 1744, has been removed. Among old mansions of interest still remaining are Strawberry Hill, the residence of Horace Walpole, now much altered; Marble Hill, built by George II. for the countess of Suffolk, and subsequently resided in by the marquis of Wellesley; Orleans House, built in the reign of Queen Anne by Johnstone, occupied for some time by the duke of Orleans, and from 1879 to 1883 as a club house; York House, said to have been the residence of James II. when duke of York, bestowed by Charles II. on Lord Clarendon when he married the duke of York's daughter, and in modern times resided in by the Comte de Paris; and Twickenham House, formerly the residence of Sir John Hawkins, author of the *History of Music*, and the meeting place of the "Literary Club." Of the old manor house of Twickenham, to which Catherine of Aragon is said to have retired after her divorce from Henry VIII., and which was subsequently the residence of Catherine of Braganza, queen of Charles II., the only remains are a ruin called the Aragon tower. Twickenham Park House, for some time the residence of Lord Chancellor Bacon, has been demolished.

TWILIGHT. The light of what is called the "sky" depends upon the scattering or reflexion of direct sunlight in the earth's atmosphere, mainly if not entirely due to those fine dust particles which (as we have recently learned) form the necessary nuclei for condensation of aqueous vapour. Were it not for these particles the sky would appear by day as it does in a clear winter night, and the stars would be always visible. Alpine climbers and aeronauts, when they have left the grosser strata of the atmosphere below them, find this state of things approximated to; and even at the sea-level the blue of the sky is darker when the air contains but few motes. After the sun has set, its rays continue for a time to pass through parts of the atmosphere above the spectator's horizon, and the scattered light from these is called twilight. It is, of course, most brilliant in the quarter where the sun has set. Before sunrise we have essentially the same phenomenon, but it goes by the name of "dawn." The brilliancy of either depends upon several conditions, of which the chief is, of course, the degree by which the sun has sunk below the horizon. But the amount of dust in the air affects the phenomenon in two antagonistic ways: it diminishes the amount of sunlight which reaches the upper air after passing close to the earth and it increases the fraction of this light which is scattered to form twilight. Hence no general law can be laid down as to the duration of twilight; but it is usual to state (roughly) that it lasts until the sun is about 18° under the horizon. If we make this assumption, it is a simple matter of calculation to solve questions as to the duration of twilight at a given place at a given time of year, the maximum duration of twilight at a given place, &c. In the older works on astronomy such questions were common enough, but they have now little beyond antiquarian interest. The more complex phenomena of twilight, such as the "after-glow," &c., probably depend upon the precipitation of moisture on the dust particles as the air becomes gradually colder. This will of course alter the amount of scattering; but it may also lead (by reflexion from strata of such particles) to an increase in the amount of light to be scattered.

TYCHO BRAHE. See **BRAHE**.

TYLDESLEY WITH **SHAKERLEY**, a town of Lancashire, England, is situated on a considerable eminence, 11 miles west-north-west of Manchester and 199 north-west of London (by the London and North-Western Railway). The church of St George, a handsome building in the Early Pointed style, erected in 1827, has lately undergone restoration. Public baths were built in 1876. A public cemetery was formed in 1878. The town is the growth of the 19th century and depends upon its cotton-mills and the large collieries in the neighbourhood. It is governed by a local board of health of sixteen members. The population of the urban sanitary district (area 2490 acres) in 1871 was 6408 and in 1881 it was 9954.

At Domesday Tyldesley formed part of the manor of Warrington. One of its proprietors, Sir Thomas Tyldesley, was a distinguished Royalist. His son Edward in 1672 sold the manor to Ralph Astley, and from the Astleys it passed in 1728 to Thomas Johnson of Bolton. In 1823 it became the property of George Ormerod, author of the *History of Cheshire*.

TYLER, JOHN (1790-1862), tenth president of the United States, was accustomed with pride, but with the support of conjecture rather than evidence, to claim relationship with Wat Tyler of the reign of Richard II. The earliest of his American ancestors was Henry Tyler, a reputed native of Shropshire, England, who in 1652 settled at Middle Plantation, Va., on the outskirts of what is now the city of Williamsburg. John Tyler was the son of Judge John Tyler, some time governor of Virginia, and was born at Greenway in that State, 29th March 1790. In 1802 he entered the grammar school of William and Mary, where, though fond of fun and frolic and cultivating an inherited taste for the violin, he made good progress in his studies. After graduating in 1806 he entered on the study of law, and in 1809 was called to the bar, where his progress from the first was rapid. He became a member of the State legislature in December 1811. In 1813 he raised a company in defence of Richmond, in command of which he subsequently served with the fifty-second regiment at Williamsburg and Providence Forge. In December 1816 he was elected to the house of representatives at Washington, where he displayed much readiness and skill in debate as an uncompromising advocate of popular rights. In 1825 he was elected governor of Virginia by a large majority, and the following year was re-elected unanimously. In 1827 he was chosen a senator. He opposed Clay on the tariff question in 1832, delivering a speech against the protective duties which lasted three days; but he voted for Clay's Compromise Bill of 1833. He was the only senator who voted against the Force Bill on 20th February of this year, a singularity of conduct which somewhat damaged his reputation in Virginia. Although opposed to the establishment of the United States Bank, he supported the resolutions in 1835 censuring President Jackson for the removal of the deposits, on the ground that the procedure was unconstitutional. In consequence of a vote of the Virginia legislature instructing him to vote for the expurgation of these resolutions from the senate journal he resigned, 21st February 1836. His action led the Whigs to bring him forward as a candidate for the vice-presidency, but he only received forty-seven votes. For some time after this he ceased to take an active part in politics; removing in the end of the year from Gloucester to Williamsburg, where he had better opportunities for legal practice, he devoted his chief attention to his professional duties. At the Whig convention which met at Harrisburg, Pennsylvania, 4th December 1839, he was nominated again for the vice-presidency on the Harrison ticket, and elected in November 1840. On the death of Harrison, soon after his inauguration in 1841, Tyler succeeded him. His ele-

vation to the presidency was thus accidental in a double sense, for he had been nominated for the vice-presidency to reconcile the extreme faction. His policy in office (see UNITED STATES) was opposed to the party who nominated him and was on Democratic lines. In 1845 he was succeeded by Polk, and he spent the remainder of his life in retirement from active duties. He was nominated in 1861 for the lower house of the permanent congress, but died at Richmond on the 18th of the following January.

See L. G. Tyler, *Life and Times of the Tylers*, 2 vols., 1884.

TYNDALE, WILLIAM (c. 1484-1536), translator of the New Testament and Pentateuch (see ENGLISH BIBLE, vol. viii. pp. 384, 385), was born in Gloucestershire, possibly in the parish of Slimbridge, about the year 1484. Of his early education nothing is known; about his twentieth year he went to Oxford, where tradition has it that he was entered of Magdalen Hall. He afterwards resided at Cambridge. Ordained to the priesthood, probably towards the close of 1521, he entered the household of Sir John Walsh, Little Sodbury, Gloucestershire, in the capacity of chaplain and domestic tutor. Here he spent two years, and in the course of his private studies began to contemplate seriously the work of translating the New Testament into English. His sympathy with the "new learning," which he had not concealed in conversation with the higher clergy of the neighbourhood at Sir John's table, led to his being summoned before the chancellor of Worcester as a suspected heretic; and "with the goodwill of his master" he left for London in the summer of 1523. There he preached a little at St Dunstan-in-the-West, and worked at his translation, living for some months in the house of Humphrey Monmouth, an alderman; but finding publication impossible in England he sailed for Hamburg in May 1524. After visiting Luther at Wittenberg, he settled in Cologne, where he made some progress with a quarto edition of his New Testament, when the interference of the authorities of the town compelled his flight to Worms. The octavo edition (see vol. viii. p. 384) was here completed in 1526. Where Tyndale resided in the interval between 1526 and 1530—the year of publication of his translation of the Pentateuch—is not known; his *Parable of the Wicked Mammon* (1527), *Obedience of a Christian Man* (1528), and *Practice of Prelates* (1530), all bear to have been printed at "Marlborowe in the land of Hesse" or "Marborch." From 1530 onwards he appears to have lived chiefly in Antwerp, but of his life there hardly anything is recorded, except that as a marked man he was continually the subject of plots and intrigues, and that at last he was arrested and thrown into prison in the castle of Vilvorde, some six miles from Brussels, in 1535. Having been found guilty of heresy, he was put to death by strangling, and his body afterwards burnt at the stake on October 6, 1536.

The *Works* of Tyndale were first published along with those of FRITH (*q.v.*) and Barnes, "three worthy Martyrs and principal Teachers of the Church of England," by John Daye, in 1573 (folio). His *Doctrinal Treatises and Introductions to Different Portions of the Holy Scripture* were published by the Parker Society in 1848. For biography, see Demaus, *William Tyndale* (London, 1871); also the Introduction to Mombert's critical reprint of Tyndale's Pentateuch (New York, 1884), where a full bibliography is given. There seems no reason to doubt that the translation of Joshua, Judges, Samuel, Kings, and Chronicles in Matthew's Bible is substantially the work of Tyndale.

TYNE, a river in the north-east of England, is formed of two branches, the North Tyne, rising in the Cheviots on the borders of Roxburgh, and the South Tyne, rising at Tynehead Fell, at the south-eastern extremity of Cumberland. The North Tyne flows south-eastwards by Bellingham, a short distance below which it receives the Rede from the north, and 2 miles above Hexham it is joined by the South Tyne, which before the junction flows north-

ward to Haltwhistle, and then eastward, receiving the Allen from the right a short distance above Haydon Bridge. The united streams then have a course of about 30 miles eastwards to the sea at Tynemouth. For a considerable part of its course the Tyne flows through a pleasant and richly cultivated country, but in its lower reaches the presence of coal pits has almost completely robbed the scenery of its natural charms, and the former sylvan retreats of monks and abbots are now occupied by blast furnaces and shipbuilding yards, and similar scenes of busy industry, which line both banks of the river from Newcastle to the sea. The river is navigable to Blaydon for small craft, and to Newcastle, 8 miles from its mouth, for large vessels.

The coal trade of the Tyne is the most important in England, and for its general shipping trade the river ranks next in importance to the Thames and the Mersey. The principal ports are Newcastle and North and South Shields, but below Newcastle the river is everywhere studded with piers and jetties. About a seventh of the whole tonnage of vessels built in England is built on the Tyne, the most important works being those of Jarrow. For boat-racing the Tyne vies in celebrity with the Thames.

TYNEMOUTH, a municipal and parliamentary borough of England, in Northumberland, includes the townships of Chirton, Cullercoates, North Shields, Preston, and Tynemouth. This last, the principal watering-place on this part of the coast, is picturesquely situated on a promontory on the north side of the Tyne at its mouth. It is connected with Newcastle, 8 miles to the west-south-west, by a branch of the North-Eastern Railway; its distance from London is 273½ miles by rail. The town has rapidly increased within recent years, and contains many well-built streets, squares, and villas. On the point of the promontory there is a small battery called the Spanish battery, and near it a monument has been erected to Lord Collingwood. Within the grounds to which the gateway of the old castle gives entrance are the ruins of the ancient priory of St Mary and St Oswin—the principal remains being those of the church. A pier, half a mile long, serves as a breakwater to the harbour. Among the principal public buildings are the assembly rooms and the aquarium (1872). The municipal buildings of the borough of Tynemouth are situated in North Shields, where are also the custom house, a master mariners' home, a seamen's institute, and a sailors' home founded by the late duke of Northumberland. Shipbuilding is carried on, and there are rope and sail works. The fish trade is of considerable importance and employs several steam and sailing boats. The population of the municipal and parliamentary borough of Tynemouth (incorporated in 1849; area 4303 acres), divided into the three wards of North Shields, Percy, and Tynemouth, was 38,941 in 1871, and 44,118 in 1881.

Tynemouth was a fortress of the Saxons, and was anciently known as Penbal Crag, "the head of the rampart on the rock." From remains found in 1783 it is supposed to have been a Roman station. The first church was built of wood by Edwin, king of Northumbria, about 625, and was rebuilt in stone by his successor Oswald in 634. The body of Oswin, king of Deira, was brought hither for burial in 651, and on this account Tynemouth came to be in great repute as a place of burial both for royal and ecclesiastical persons. The monastery was repeatedly plundered and burnt by the Danes, especially during the 9th century. After its destruction by Healfdeane in 876 it was rebuilt by Tostig, earl of Northumberland, who endowed it with considerable revenue; but, having been granted in 1074 to the monks of Jarrow, it became a cell of Durham. Malcolm III., king of the Scots, and his son Edward, who were slain in battle at Alnwick on 13th November 1093, were both interred in the monastery. In 1095 Earl Mowbray, having entered into a conspiracy against William Rufus, converted the monastery into a castle, which he strongly fortified. By William Rufus the priory was conferred on St Albans abbey, Hertfordshire. It was surrendered to Henry VIII. on 12th January 1539, and the site and remains were granted by Edward VI. in 1550 to the earl of Warwick, afterwards duke of Northumberland. In 1644 the castle was taken by the Scots under the earl of Leven. The town enjoyed various immunities at a very early period, which were

afterwards the subject of some dispute. Edward I. restored to it several free customs of which it had been deprived. Afterwards it received a confirmation of its various former charters by Edward II. and Richard II.

TYPE-FOUNDING. See TYPOGRAPHY.

TYPE-WRITING. See WRITING MACHINES.

TYPHON, or TYPHOEUS, son, according to Hesiod (*Theog.*, 820 sq.), of the Earth and Tartarus, is described as a grisly monster with a hundred dragons' heads who was conquered and cast into Tartarus by Zeus. According to *Iliad* ii. 282, he lies in the land of the Arimi (Cilicia). Other legends place his prison under Ætna or in other volcanic regions and make him the cause of eruptions. The myth, therefore, as we have it, rests on a personification of volcanic forces. He is the father of dangerous winds (typhoons), and by later writers is identified with the Egyptian Set (see vol. vii. p. 717).

TYPHUS, TYPHOID, AND RELAPSING FEVERS. These are conveniently considered together, as they constitute the important class of continued fevers, having certain characters in common, although each is clearly distinguishable from the others. The following is a general account of the more salient features of each.

TYPHUS FEVER.

Typhus¹ is a continued fever of highly contagious nature, lasting for about fourteen days and characterized mainly by great prostration of strength, severe nervous symptoms, and a peculiar eruption on the skin. It has received numerous other names, such as spotted, pestilential, putrid, jail, hospital fever, &c. It appears to have been known for many centuries as a destructive malady, frequently appearing in epidemic form, in all countries in Europe, under the conditions to be afterwards referred to. The best accounts of the disease are those given by English writers, who narrate its ravages in towns and describe many "black assizes," in which it was communicated by prisoners brought into court to the judges, jurymen, court-officials, &c., with fatal effect, producing oftentimes a widespread consternation. Typhus fever would seem to have been observed in almost all parts of the world; but, although not unknown in warm countries, it has most frequently prevailed in temperate or cold climates.

The causes concerned in its production include both the predisposing and the exciting. Of the former the most powerful of all are those influences which lower the health of a community, especially overcrowding and poverty. Hence this fever is most frequently found to affect the poor of large cities and towns, or to appear where large numbers of persons are living crowded together in unfavourable hygienic conditions, as has often been seen in prisons, workhouses, &c. Armies in the field are also liable to suffer from this disease; for instance, during the Crimean War it caused an enormous mortality among the French troops. Some high authorities, including Dr Murchison, have held that such conditions as those referred to are capable of generating typhus fever by themselves, and the apparent occasional *de novo* origin of this disease has doubtless the support of many striking facts which would appear to favour this view (see *PATHOLOGY*, vol. xviii. p. 803). In the light, however, of recent researches into the relation of specific disease germs to the production of fevers and other infectious maladies, there is increasing difficulty in maintaining this position; and the direction of opinion is decidedly towards the view that, however much insanitary conditions and overcrowding act as causes predisposing to the reception of the disease, the introduction into the system of a living organism or germ is necessary to the manifestation of the phenomena of the fever. Nevertheless no specific organism has yet been clearly identified

¹ From *τυφος*, smoke or mist, in allusion to the stupor of the disease.

in the case of typhus fever. This disease is now much less frequently encountered in medical practice than formerly, — a fact which must mainly be ascribed to the great attention which in recent times has been directed to improvement in the sanitation of towns, especially to the opening up of crowded localities so as to allow the free circulation through them of fresh air. In most large cities, however, limited epidemic outbursts of the disease occur from time to time, under the conditions of overcrowding and poverty, although the increased facilities possessed by local authorities for recognizing such outbreaks, and for the prompt isolation or removal of infected persons to hospitals, operate in general effectually to prevent any extensive spread of the fever. All ages are liable to typhus, but the young suffer less severely than the old. The disease appears to be communicated by the exhalations given off from the bodies of those suffering from the fever, and those most closely in contact with the sick are most apt to suffer. This is shown by the frequency with which nurses and physicians take typhus from cases under their care. As in all infectious maladies, there is often observed in typhus a marked proclivity to suffer in the case of individuals, and in such instances very slight exposure to the contagion may convey the disease. Typhus is highly contagious throughout its whole course and even in the early period of convalescence. The contagion, however, is rendered less active by the access of fresh air; hence this fever rarely spreads in well-aired rooms or houses where cases of the disease are under treatment. As a rule one attack of typhus confers immunity from risk of others, but numerous exceptions have been recorded.

The course of typhus fever is characterized by certain well-marked stages. (1) The stage of *incubation*, or the period elapsing between the reception of the fever poison into the system and the manifestation of the special evidence of the disease, is believed to vary from a week to ten days. During this time, beyond feelings of languor, no particular symptoms are exhibited. (2) The *invasion* of the fever is in general well marked and severe, in the form of a distinct rigor, or of feelings of chilliness lasting for hours, and a sense of illness and prostration, together with headache of a distressing character and sleeplessness. Feverish symptoms soon appear and the temperature of the body rises to a considerable height (103°-105° Fahr.), at which it continues with but little daily variation until about the period of the crisis. It is, however, of importance to observe certain points connected with the temperature during the progress of this fever. Thus about the seventh day the acme of the fever heat has been reached, and a slight subsidence (1° or less) of the tem-

Temperature chart of typhus fever.

perature takes place in favourable cases, and no further subsequent rise beyond this lowered level occurs. When it is otherwise, the case often proves a severe one. Again, when the fever has advanced towards the end of the second week, slight falls of temperature are often observed, prior to the extensive descent which marks the attainment of the crisis. The pulse in typhus fever is rapid (100-120

Predis-
posing
and ex-
citing
causes.

or more) and at first full, but later on feeble. Its condition as indicating the strength of the heart's action is watched with anxiety. The tongue, at first coated with a white fur, soon becomes brown and dry, while sordes (dried mucus, &c.) accumulate upon the teeth; the appetite is gone and intense thirst prevails. The bowels are as a rule constipated, and the urine is diminished in amount and high-coloured. The physician on examination may make out distinct enlargement of the spleen. (3) The third stage is characterized by the appearance of the *eruption* which generally shows itself about the fourth or fifth day or later, and consists of dark red (mulberry coloured) spots or blotches varying in size from mere points to three or four lines in diameter, very slightly elevated above the skin, at first disappearing on pressure, but tending to become both darker in hue and more permanent. They appear chiefly on the abdomen, sides, back, and limbs, and occasionally on the face. Besides this, the characteristic typhus rash, there is usually observed a general faint mottling all over the surface. The typhus rash is rarely absent and is a very important diagnostic of the disease. In the more severe and fatal forms of the fever, the rash has all through a very dark colour, and slight subcutaneous hæmorrhages (*petechiæ*) are to be seen in abundance. After the appearance of the eruption the patient's condition seems to be easier, so far as regards the headache and discomfort which marked the outset of the symptoms; but this is also to be ascribed to the tendency to pass into the typhous stupor which supervenes about this time, and becomes more marked throughout the course of the second week. The patient now lies on his back, with a dull dusky countenance, an apathetic or stupid expression, and contracted pupils. All the febrile symptoms already mentioned are fully developed, and delirium, usually of a low muttering kind, but sometimes wild and maniacal (*delirium ferox*) is present both by night and day. The peculiar condition to which the term "coma vigil" is applied, in which the patient, though quite unconscious, lies with eyes widely open, is regarded, especially if persisting for any length of time, as an unfavourable omen. Throughout the second week of the attack the symptoms continue unabated; but there is in addition great prostration of strength, the pulse becoming very feeble, the breathing shallow and rapid, and often accompanied with bronchial sounds. (4) A *crisis* or favourable change takes place about the end of the second or beginning of the third week (on an average the 14th day), and is marked by a more or less abrupt fall of the temperature (*vide* chart) and of the pulse, together with slight perspiration, a discharge of loaded urine, the return of moisture to the tongue, and by a change in the patient's look, which clears up and shows signs of returning intelligence. Although the sense of weakness is extreme, convalescence is in general steady and comparatively rapid.

Typhus fever may, however, prove fatal during any stage of its progress and in the early convalescence, either from sudden failure of the heart's action—a condition which is specially apt to arise—from the supervention of some nervous symptoms, such as meningitis or of deepening coma, or from some other complication, such as bronchitis. Further, a fatal result sometimes takes place before the crisis from sheer exhaustion, particularly in the case of those whose physical or nervous energies have been lowered by hard work, inadequate nourishment and sleep, or intemperance, in all which conditions typhus fever is apt to assume an unusually serious form.

Occasionally troublesome sequelæ remain behind for a greater or less length of time as the effects of the fever. Among these may be mentioned mental weakness or irritability, occasionally some form of paralysis, an inflamed condition of the lymphatic vessels of one leg (the swelled leg of fever), prolonged weakness and ill health, &c. Gradual improvement, however, may be confidently anticipated and even ultimate recovery.

Mortality. The mortality from typhus fever is estimated by Murchison and others as averaging about 18 per cent. of the cases, but it varies

much according to the severity of type (particularly in epidemics), the previous health and habits of the individual, and very specially the age,—the proportion of deaths being in striking relation to the advance of life. Thus, while in children under fifteen the death-rate is only 5 per cent., in persons over fifty it is about 46 per cent.

The treatment of typhus fever includes the prophylactic measures Treatment of attention to the sanitation of the more densely populated portions of towns. The opening up of cross streets intersecting those which are close-built and narrow, whereby fresh air is freely admitted, has done much to banish typhus fever from districts where previously it was endemic. Further, the enforcement of the law regulating the number of persons accommodated in common lodging-houses, and the application of the powers now vested in local authorities for dealing with cases of overcrowding everywhere, and for isolation and treatment of the infected, have had a like salutary effect. Where typhus has broken out in a crowded district the prompt removal of the patients to a fever hospital and the thorough disinfection and cleansing of the infected houses are to be recommended. Where, on the other hand, a single case of accidentally caught typhus occurs in a member of a family inhabiting a well-aired house, the chance of it being communicated to others in the dwelling is but small; nevertheless every precaution in the way of isolation and disinfection should be taken.

The treatment of a typhus patient is conducted upon the same general principles as have been illustrated in other fevers (see SCARLET FEVER, SMALLPOX). Complete isolation should be maintained throughout the illness, and the services of a day and a night nurse procured, who should keep a strict watch and preserve a record of the temperature and other observations, the times of feeding and the form of nourishment administered, as well as every other fact noticed, for the physician's information. Due attention should be given to the ventilation and cleansing of the sick chamber. The main element in the treatment of this fever is good nursing, and especially the regular administration of nutriment, of which the best form is milk, although light plain soup may also be given. The food should be administered at stated intervals, not, as a rule, oftener than once in one and a half or two hours, and it will frequently be necessary to rouse the patient from his stupor for this purpose. Sometimes it is impossible to administer food by the mouth, in which case recourse must be had to nutrient enemata. Alcoholic stimulants are not often required, except in the case of elderly and weakly persons who have become greatly exhausted by the attack and are threatening to collapse. The best indication for their use is that furnished by the condition of the circulation: when the pulse shows unsteadiness and undue rapidity, and the first sound of the heart is but indistinctly heard by the stethoscope, the prompt administration of stimulants (of which the best form is pure spirit) will often succeed in averting danger. Should their use appear to increase the restlessness or delirium they should be discontinued and the diffusible (ammoniacal or ethereal) forms tried instead.

Many other symptoms demand special treatment. The headache, which persists for days at the commencement and is with many a very distressing symptom, may be mitigated by removing the hair and applying cold to the head. The sleeplessness, with or without delirium, may be combated by quietness, by a moderately darkened room (although a distinction between day and night should be made as regards the amount of admitted light), and by soothing and gentle dealing on the part of the nurse. Opiate and sedative medicines in any form, although recommended by many high authorities, must be given with great caution, as their use is often attended with danger in this fever, where coma is apt to supervene. When resorted to, probably the safest form is a combination of the bromide of potassium or ammonium with a guarded amount of chloral. The writer has seen alarming effects follow the administration of opium. Occasionally the deep stupor calls for remedies to rouse the patient, and these may be employed in the form of mustard or cantharides to the surface (calves of legs, nape of neck, over region of heart, &c.), of the cold affusion, or of enemata containing turpentine. The height of the temperature may be a serious symptom, and antipyretic remedies appear to have but a slight influence over it as compared to that which they possess in typhoid fever, acute rheumatism, &c. The cold bath treatment, which has been recommended, cannot be carried out without serious risk to life in the necessary movement of the patient. It is a well-recognized rule that persons suffering from typhus fever ought not to be moved up in bed for any purpose after the first few days. Cold sponging of the hands and feet and exposed parts, or cold to the head, may often considerably lower the temperature. Throughout the whole progress of a case the condition of the bladder requires special attention, owing to the patient's drowsiness, and the regular use of the catheter becomes, as a rule, necessary with the advance of the symptoms.

The complications and results of this fever fall to be dealt with according to the methods of treatment applicable to their character and extent.

TYPHOID OR ENTERIC FEVER.

Typhoid or enteric fever (έντερον, the intestine) is a continued fever characterized mainly by its insidious onset, by a peculiar course of the temperature, by marked abdominal symptoms occurring in connexion with a specific lesion of the bowels, by an eruption upon the skin, by its uncertain duration, and by a liability to relapses.

This fever has received various names, such as gastric fever, abdominal typhus, infantile remittent fever, slow fever, nervous fever, &c. Dr Murchison, in reference to its supposed origin in putridity, uses the term "pythogenic fever," but this designation has not been generally adopted. Up till a comparatively recent period typhoid was not distinguished from typhus fever. For, although it had been noticed that the course of the disease and its morbid anatomy were different from those of ordinary cases of typhus, it was believed that they merely represented a variety of that malady. The distinction between the two diseases appears to have been first accurately made in 1836 by Messrs Gerhard and Pennock of Philadelphia, and still more fully demonstrated by Dr A. P. Stewart of Glasgow (afterwards of London). Subsequently all doubt upon the subject was removed by the careful clinical and pathological observations made by Sir William Jenner at the London fever hospital (1849-51). A clear distinction has been established between the two fevers, not only as regards their phenomena or morbid features, but equally as regards their origin. While typhus fever is a disease of overcrowding and poverty, typhoid may occur where such conditions are entirely excluded; and the connexion of this malady with specific emanations given off from decomposing organic or fæculent matters, or with contamination of food or water by the products of the disease, is now almost universally admitted. Alike in sporadic cases and in extensive epidemic outbreaks the existence of insanitary conditions in house drainage, water supply, &c., can in the majority of instances be made out. The question whether such conditions alone will suffice to beget this fever—or, in other words, its *de novo* origin—has, as in the case of typhus, been much discussed, and an affirmative opinion expressed by some high authorities. But the same remark must again be made as to the difficulties in the way of maintaining such a position in view of the evidence of the part played by microbes in infective processes.

Nature
of
typhoid.

Causes of
its out-
break.

That all insanitary conditions in respect of drainage of houses and localities furnish the most ready means for the introduction of the contagion of typhoid there is a general agreement, as there is equally that the most certain means of preventing its appearance or spread are those which provide a thoroughly trustworthy and secure drainage, a safe method of disposal of sewage, and a pure and abundant water supply. Typhoid fever is much less directly communicable from the sick to the healthy than typhus. The infective agent appears to reside in the discharges from the bowels, in which, particularly when exposed and undergoing decomposition, the contagium seems to multiply and to acquire increased potency. Thus in sewers, drains, &c., in association with putrefying matter, it may increase indefinitely, and by the emanations given off from such decomposing material accidentally escaping into houses, or by the contamination of drinking water in places where wells or cisterns are exposed to fæcal or sewage pollution, the contagion is conveyed. Of the precise nature of the contagious principle we have as yet no full information,¹ but there appears to be strong reason for believing that a specific microbe or organism plays a part in the propagation of the disease. Still it is obvious that for its successful

implantation in and effect upon the system a peculiar condition of preparedness or receptivity to the morbid agent must be presupposed to exist in the individual, regarding which also our knowledge is of the vaguest. There is abundant evidence that one of the vehicles for the conveyance of the contagion is food, especially milk, which may readily become contaminated with the products of the disease where an outbreak of the fever has occurred in a dairy.

Typhoid fever is most common among the young, the majority of the cases occurring between the ages of fifteen and twenty-five (Murchison). But children of any age may suffer, as may also, though more rarely, persons at or beyond middle life. It is of as frequent occurrence among the well-to-do as among the poor. The greater number of cases appear to occur in autumn. In all countries this fever seems liable to prevail; and, while some of its features may be modified by climate and locality, its main characters and its results are essentially the same everywhere.

The more important phenomena of typhoid fever will be better understood by a brief reference to the principal pathological changes logical which take place during the disease. These relate for the most part changes to the intestines, in which the morbid processes are highly characteristic, both as to their nature and their locality. The changes (to typhoid, be presently specified) are evidently the result of the action of the contagium on the system, and they begin to show themselves from the very commencement of the fever, passing through various stages during its continuance. The portion of the bowels in which they occur most abundantly is the lower part of the small intestine (ileum), where the "solitary glands" and "Peyer's patches" on the mucous surface of the canal become affected by diseased action of a definite and progressive character, which stands in distinct relation to the symptoms exhibited by the patient in the course of the fever. (1) These glands, which in health are comparatively indistinct, become in the commencement of the fever enlarged and prominent by infiltration due to inflammatory action in their substance, and consequent cell proliferation. This change usually affects a large extent of the ileum, but is more marked in the lower portion near the ileo-cæcal valve (see ANATOMY). It is generally held that this is the condition of the parts during the first eight or ten days of the fever. (2) These enlarged glands next undergo a process of sloughing, the inflammatory products being cast off either in fragments or *en masse*. This usually takes place in the second week of the fever. (3) Ulcers are thus formed varying in size according to the gland masses which have sloughed away. They may be few or many in number, and they exhibit certain characteristic appearances. Thus they are frequently, but not always, oblong in shape, with their long axis in that of the bowel, and they have somewhat thin and ragged edges. They may extend through the thickness of the intestine to the peritoneal coat and in their progress erode blood-vessels or perforate the bowel. This stage of ulceration exists from the second week onwards during the remaining period of the fever, and even into the stage of convalescence. (4) In most instances these ulcers heal by cicatrization, leaving, however, no contraction of the calibre of the bowel. This stage of healing evidently occupies a considerable time, since the process does not advance at an equal rate in the case of all the ulcers, some of which have been later in forming than others. Even when convalescence has been apparently completed, some unhealed ulcers may yet remain and prove, particularly in connexion with errors in diet, a cause of relapse of some of the symptoms, and even of still more serious or fatal consequences. The mesenteric glands external to, but in functional relation with, the intestine, become enlarged during the progress of the fever, but usually subside after recovery.

Besides these changes, which are well recognized, others more or less important are often present. Among these may be mentioned one which the present writer has repeatedly observed in the severe and protracted forms of this fever, namely, marked atrophy, thinning, and softness of the coats of the intestines, even after the ulcers have healed,—a condition which may not improbably be the cause of that long-continued impairment of the function of the bowels so often complained of by persons who have passed through an attack of typhoid fever. Other changes common to most fevers are also to be observed, such as softening of the muscular tissues generally, and particularly of the heart, and evidences of complications affecting chest or other organs, which not unfrequently arise. The swelled leg of fever sometimes follows typhoid, as does also periosteal inflammation.

The symptoms characterizing the onset of typhoid fever are very much less marked than those of most other fevers, and the disease of the in the majority of instances sets in somewhat insidiously. Indeed, it is no uncommon thing for patients with this fever to go about for a considerable time after its action has begun. The most marked of the early symptoms are headache, lassitude, and discomfort, together with sleeplessness and feverishness, particularly at night; this last symptom is that by which the disease is most readily detected in its early stages. The peculiar course of the temperature,

¹ A bacillus frequently noticed in certain tissues in cases of typhoid fever has not yet been satisfactorily proved to be an organism characteristic of that disease, nor even to be constantly present.

is also one of the most important diagnostic evidences of this fever. During the first week it has a morning range of moderate febrile rise, but in the evening there is a marked ascent, with a fall again towards morning, each morning and evening, however, showing respectively a higher point than that of the previous day, until about the eighth day, when in an average case the highest point is attained. This varies according to the severity of the attack;

Temperature chart of typhoid fever.

but it is no unusual thing to register 104° or 105° Fahr. in the evening and 103° or 104° in the morning. During the second week the daily range of temperature is comparatively small, a slight morning remission being all that is observed. In the third week the same condition continues more or less; but frequently a slight tendency to lowering may be discerned, particularly in the morning temperature, and the febrile action gradually dies down as a rule between the twenty-first and twenty-eighth days, although it is liable to recur in the form of a relapse. Although the patient may, during the earlier days of the fever, be able to move about, he feels languid and uneasy; and usually before the first week is over he has to take to bed, and soon the effects of the attack become more apparent. He is restless, hot, and uncomfortable, particularly as the day advances, and his cheeks show a red flush, especially in the evening or after taking food. The aspect, however, is different from the oppressed stupid look which is present in typhus, and more resembles the appearance of hectic. The pulse in an ordinary case, although more rapid than normal, is not accelerated to an extent corresponding to the height of the temperature, and is, at least in the earlier stages of the fever, rarely above 100°. In severe and protracted cases, where there is evidence of extensive intestinal ulceration, the pulse becomes rapid and weak, with a dirotic character indicative of cardiac feebleness. The tongue has at first a thin whitish fur and is red at the tip and edges. It tends, however, to become dry, brown or glazed looking, and fissured transversely, while *sordes* may be present about the lips and teeth. There is much thirst and in some cases vomiting. Splenic and hepatic enlargement may be made out. From an early period in the disease abdominal symptoms show themselves with greater or less distinctness and are frequently of highly diagnostic significance. The abdomen is somewhat distended or tumid, and pain accompanying some gurgling sounds may be elicited on light pressure about the lower part of the right side close to the groin,—the region corresponding to that portion of the intestine in which the morbid changes already referred to are progressing. Diarrhoea is a frequent but by no means constant symptom. When present it may be slight in amount, or, on the other hand, extremely profuse, and it corresponds as a rule to the severity of the intestinal ulceration. The discharges are highly characteristic, being of light yellow colour resembling pea soup in appearance. Should intestinal hæmorrhage occur, as is not infrequently the case during some stage of the fever, they may be dark brown, or composed entirely of blood. The urine is scanty and high-coloured. About the beginning, or during the course of the second week of the fever, an eruption frequently makes its appearance on the skin. It consists of isolated spots, oval or round in shape, of a pale pink or rose colour, and of about one to one and a half lines in diameter. They are seen chiefly upon the abdomen, chest, and back, and they come out in crops, which continue for four or five days and then fade away. At first they are slightly elevated, and disappear on pressure. In some cases they are very few in number, and their presence is made out with difficulty; but in others they are numerous and sometimes show themselves upon the limbs as well as upon the body. They do not appear to have any relation to the severity of the attack, and in a very considerable proportion of cases (particularly in children) they are entirely absent. Besides this eruption there are not unfrequently numerous very faint bluish patches or blotches about half an inch in diameter, chiefly upon the body and thighs. When present the rose-coloured spots continue to come out in crops till nearly the end of the fever, and they may reappear should a relapse subsequently occur. These various symptoms persist throughout the third week, usually, however, increasing in intensity. The patient becomes prostrate and emaciated; the tongue is dry and brown, the pulse quickened and feeble, and the abdominal symptoms more marked; while nervous disturbance is exhibited in delirium, in

tremors and jerkings of the muscles (*subsultus tendinum*), in drowsiness, and occasionally in "coma vigil." In severe cases the exhaustion reaches an extreme degree, although even in such instances the condition is not to be regarded as hopeless. In favourable cases a change for the better may be anticipated between the twenty-first and twenty-eighth days, more usually the latter. It does not, however, take place as in typhus by a well-marked crisis, but rather by what is termed a "lysis" or gradual subsidence of the febrile symptoms, especially noticeable in the daily decline of both morning and evening temperature, the lessening of diarrhoea, and improvement in pulse, tongue, &c. Convalescence proceeds slowly and is apt to be interrupted by relapses (due not unfrequently to errors in diet), which are sometimes as severe and prolonged as the original attack, and are attended with equal or even greater risks. Should such relapses repeat themselves, the case may be protracted for two or three months, but this is comparatively rare.

Death in typhoid fever usually takes place from one or other of the following causes. (1) Exhaustion, in the second or third weeks, death in or later. The attending symptoms are increasing emaciation, weakness of the pulse, and cadaveric aspect. Sometimes sinking is sudden, partaking of some of the characters of a collapse. (2) Hæmorrhage from the intestines. The evidence of this is exhibited, not only in the evacuations, but in the sudden fall of temperature and rise in pulse-rate, together with great pallor, faintness, and rapid sinking. Sometimes hæmorrhage, to a dangerous and even fatal extent, takes place from the nose. (3) Perforation of an intestinal ulcer. This gives rise, as a rule, to sudden and intense abdominal pain, together with vomiting and signs of collapse, viz., a rapid flickering pulse, cold clammy skin, and the marked fall of temperature. Symptoms of peritonitis (see PERITONITIS) quickly supervene and add to the patient's distress. Death usually takes place within 24 hours. Occasionally peritonitis, apart from perforation, is the cause of death. (4) Occasionally, but rarely, hyperpyrexia (excessive fever). (5) Complications, such as pulmonary or cerebral inflammation, bedsores, &c.

Certain sequelæ are sometimes observed, the most important being the swelled leg, periostitis affecting long bones, general ill-health, and anæmia, with digestive difficulties, often lasting for a long time, and sometimes issuing in phthisis. Occasionally, after severe cases, mental weakness is noticed, but it is usually of comparatively short duration.

The mortality in typhoid fever varies with the character of the Morbidity, the general health and surroundings of the individuals attacked, and other conditions. At one time it was regarded as, on an average, about the same as that of typhus; but under modern methods of treatment the chances of recovery are much greater, and the death-rate may be stated as about 12 per cent. or perhaps somewhat less.

The treatment embraces those prophylactic measures which aim at preventing the escape of sewer gases into dwelling-houses by careful attention to the drainage and plumber-work, and also secure an abundant supply of pure water for domestic use (see HYGIENE, SEWERAGE, and VENTILATION). When an outbreak of the fever occurs in a family, all such matters should be specially inquired into, and the sources of milk supply carefully scrutinized. The discharges from the bowels of the typhoid patient should be at once disinfected with carbolic acid or other similar agent, and the greatest care taken as to their disposal, with the view of obviating any risk of contamination of drinking-water, &c. The general management is conducted upon the same principles as are observed in the case of typhus, except that in typhoid fever very special care is necessary in regard to diet. Milk, the great value of which as a fever-food was first clearly set forth by Prof. Gairdner, is of eminent service in typhoid, but it must be administered with due regard to time and to the digestive powers of the patient. When given too frequently or in too great quantity it may, by its imperfect digestion, prove a source of irritation to the bowels. Even when given with every care it may fail to agree, as is proved by the presence of undigested curd in the evacuations. In such a case its admixture with lime water or with peptonizing agents may render its digestion less difficult, but sometimes its use must for a time be suspended. It is however, rare that milk cannot be borne when carefully administered. Barley water or simple soups, such as chicken broth, beef-tea, &c., are occasionally useful either as substitutes for or adjuncts to milk. All through the fever the patient should be fed at regular periods—not, as a rule, oftener than once in one and a half or two hours—although in the intervals water or other fever-drink may be given from time to time. In convalescence the diet should still be largely milk and soft matters, such as custards, light puddings, meat jellies, boiled bread and milk, &c., but other solid foods, with the exception of fish, should be for a long time avoided. In changing the diet it is of importance to note its effect upon the temperature, which may sometimes be considerably disturbed from this cause, even after the apparent subsidence of all febrile action. Stimulants, although unnecessary in a large proportion of cases, are occasionally called for when there is great exhaustion, and in prolonged attacks. Their effect, however, should be care-

fully watched. They are usually best administered in the form of pure spirit.

The more prominent symptoms which mark the course of typhoid fever frequently call for special treatment. Thus, when the fever continues long, with little break in its course, the employment of remedies to control its action (antipyretics) may often be resorted to with benefit. Such drugs as quinine, salicin, salicylic acid, and salicylate of soda, kairin, antipyrin, antifebrin, &c. (in ten to thirty grain doses of one or other), may frequently break in upon the continuity of the fever, and by markedly lowering the temperature relieve for a time the body from a source of waste, and aid in tranquillizing the excited nervous system. The times for their administration are either one or two hours before the usual maximum temperature or during the period of remission. These remedies may, however, fail, or by inducing sickness or great prostration and depression of the circulation require to be discontinued. For a similar purpose the cold bath is recommended by many high authorities and is regularly employed in Germany. The method recommended by Liebermeister is this: "When the temperature rises above 104° Fahr., the patient should be placed in a bath of about 94°, which is gradually cooled down by the addition of cold water to 68° Fahr., and remain immersed for twenty or thirty minutes, the limbs being all the while gently rubbed. He should then be put back into bed." Another method is that of Dr Brand of Stettin: "When the patient's temperature attains 102° Fahr., he should be placed in a tepid bath of 70° and allowed to remain till a sense of coldness or shivering is produced, which usually occurs in from five to twenty minutes." By such means no doubt the temperature can often be reduced 2° or 3° Fahr., but it is very apt to rise again and the bath must then be repeated. It is claimed by the advocates of this method of treatment that it has been successful in diminishing greatly the mortality of typhoid fever, but they hold at the same time that its success in large measure depends upon its employment from an early stage in the disease. British physicians are much divided upon the point, many high authorities agreeing in its marked utility, while others no less eminent regard it as fraught with danger from the frequent movement of the patient from bed, the shock to the system, and the risk of hæmorrhage, pneumonia, or other complications, and as a plan of treatment difficult of being carried out in ordinary practice. Although employed in some fever hospitals and with apparent success, it has not yet commended itself for general adoption. Other methods of applying cold, while probably less effectual than the bath, are much more available, as, for example, the tepid or cold pack, the frequent sponging of portions of the body with cold water, or the application of icebags to the head. The present writer has resorted to these methods in many cases of typhoid fever, with the effect of markedly lowering a high temperature. When diarrhoea is excessive it may be restrained by such remedies as chalk, bismuth, Dover's powder, &c. Hæmorrhage is dealt with by preparations of ergot, or by acetate of lead, gallic acid, or other styptics. In the event of perforation of the bowel opium is the only means available to lessen the distress attending that fatal occurrence.

In the convalescent stage, and even after apparently complete recovery, the utmost care should be observed by the patient as to diet, all hard and indigestible substances being dangerous from their tendency to irritate or reopen unhealed ulcers, and bring on a relapse of the fever or cause a sudden perforation. Lastly, the general health demands careful attention for a length of time, in view of the remoter risks of chest and other diseases already alluded to.

RELAPSING FEVER.

This is a continued fever occasionally appearing as an epidemic in communities suffering from scarcity or famine. It is characterized mainly by its sudden invasion, with violent febrile symptoms, which continue for about a week and end in a crisis, but are followed, after another week, by a return of the fever.

This disease has received many other names, the best known of which are famine fever, short fever, synocha, bilious relapsing fever, recurrent typhus, and spirillum fever. As in the case of typhoid, relapsing fever was long believed to be simply a form of typhus. The distinction between them appears to have been first clearly established in 1826, in connexion with an epidemic in Ireland. Outbreaks of relapsing fever have occurred in all parts of the world at times and in places where famine has arisen; but the disease has been most closely observed and studied in epidemics in Great Britain and Ireland, Germany, Poland, Russia, America, and India. It has frequently been found to prevail along with an epidemic of typhus fever.

Relapsing fever is highly contagious, and appears, like typhus, to be readily communicated by the exhalations from the body. With respect to the nature of the contagion, certain important and interesting observations have been made. In 1873 Obermeier discovered in the blood of persons suffering from relapsing fever minute organisms in the form of spiral filaments of the genus *Spirorchæta* (see vol. xxi. p. 399, fig. 1, n), measuring in length $\frac{1}{100}$ to $\frac{1}{80}$ inch and in breadth $\frac{1}{1000}$ to $\frac{1}{500}$ inch, and possessed of rotatory or twisting movements. This organism has received the name of *Spirillum obermeieri*. It appears to be present in abundance during the height of the febrile symptoms, and is not seen during the interval until the relapse is impending, when it is again present as before. This observation has been confirmed by numerous investigators, and it has been found that inoculation with the blood containing these *Spirilla* produced the symptoms of relapsing fever in both men and animals. Comparatively little is as yet known of the life-history of these organisms, and the question whether they are to be regarded as the prime source of the disease or as mere accompaniments affords ground for difference of opinion (see PATHOLOGY, vol. xviii. p. 403); nevertheless their discovery and the conditions of their presence already mentioned are noteworthy facts in reference not only to the pathology of this fever but also to the general doctrine of infectiveness in disease-processes. The most constantly recognized factor in the origin and spread of relapsing fever is destitution; but this cannot be regarded as more than a predisposing cause favouring the reception and propagation of the morbid agent, since in many lands widespread and destructive famines have prevailed without any outbreak of this fever. Instances, too, have been recorded where epidemics were distinctly associated with overcrowding rather than with privation. Relapsing fever is most commonly met with in the young. One attack does not appear to protect from others, but rather, according to some authorities, engenders liability.

The extreme contagiousness of relapsing fever has occasionally been shown by its spreading widely when introduced into a district, even among those who had not become predisposed by destitution or other depressing conditions. The contagion, like that of typhus, appears to be most active in the immediate vicinity of the patient and to be greatly lessened by the access of fresh air. It is capable of being conveyed by clothing. The incubation of the disease is about one week. The symptoms of the fever then show themselves with great abruptness and violence by a rigor, accompanied with pains in the limbs and severe headache. The febrile phenomena are very marked, and the temperature quickly rises to a high point

Temperature chart of relapsing fever.

(105°-107° Fahr.), at which it continues with little variation, while the pulse is rapid (100-140), full, and strong. There is intense thirst, a dry brown tongue, bilious vomiting, tenderness over the liver and spleen, and occasionally jaundice. Sometimes a peculiar bronzy appearance of the skin is noticed, but there is no characteristic rash as in typhus. There is much prostration of strength. After the continuance of these symptoms for a period of from five to seven days, the temperature suddenly falls to the normal point or below it, the pulse becomes correspondingly slow, and a profuse perspiration occurs, while the severe headache disappears and the appetite returns. Except for a sense of weakness, the patient feels well and may even return to work, but in some cases there remains a condition of great debility, accompanied with rheumatic pains in the limbs. This state of freedom from fever continues for about a week, when there occurs a well-marked relapse with scarcely less abruptness and severity than in the first attack, and the whole symptoms are of the same character, but they do not, as a rule, continue so long, and they terminate in a crisis in three or four days, after which convalescence proceeds satisfactorily. Second, third, and even fourth relapses, however, may occur in exceptional cases.

The mortality in relapsing fever is comparatively small, about 5 Morper cent. being the average death-rate in epidemics (Murchison). The fatal cases occur mostly from the complications common to &c. continued fevers. The treatment is essentially the same as that for typhus fever (see above). (J. O. A.)

TYPOGRAPHY

PART I.—HISTORICAL.

TYPOGRAPHY (writing by types) is the art of printing (cast-metal) movable types on paper, vellum, &c. It is quite distinct, not only from writing, but from xylography or wood-engraving, *i.e.*, the art of cutting figures, letters, or words on blocks of wood and taking impressions from such blocks, by means of ink or any other fluid coloured substance, on paper or vellum.

Earliest definitions.

Possibly the earliest attempt to describe the art of typography is that in the *Donatus* issued by Peter Schoeffer, perhaps before 1456, the colophon of which says that it was finished "Arte nova imprimendi seu caracterizandi [from *character* = letter] . . . absque calami exaratione." Fust and Schoeffer in the Mainz psalter of 1457 said that it was formed by an "adinventio artificiosa imprimendi ac caracterizandi absque calami ulla exaratione." The colophon of the *Catholicon* of 1460 is more precise, and says that the book was printed "non calami, stili, aut penne suffragio, sed mira patronarum formarumque concordia, proporcione, ac modulo." In 1462 Albrecht Pfister had "gedrucket" the *Four Histories*. In the *Liber Sextus Decretalium*, published in 1465, Fust and Schoeffer say that it was completed "non atramento [atramento communi, in the Justinianus of 1468 and 1472], plumali canna neque aerea, sed artificiosa quadam adinventione imprimendi seu caracterizandi," a phrase which they slightly varied in Cicero's *Officia*, issued in the same year: "non atramento, plumali canna neque aerea, sed arte quadam perpulcra." The edition of St. Jerome's *Epistles* of 1470 is said to have been completed by an "ars impressoria," the *Decretum Gratiani* of 1472 by an "ars quadam ingeniosa imprimendi," the *Dyalogus* of 1473 by an "ars magistra." We find further—"ars sancta" or "divina," "nova ars scribendi," "novum exscribendi genus prope divinum," "sculptoria archetyporum ars," "ars mirifica formandi," "ars excusoria," "nova imprimendi ratio," "ars pressura," "chalcotypa ars," "chalcographia" (1472 and later), "chalcographia excusoria impressoriaque," "libraria impressio," "empryntye" (Caxton, 1482), "prenterei" (Schoeffer, 1492), "truckery" (1505), "impression des livres" (1498), and "prenten."

Printers.

The early printers called themselves, or were called by others, "librorum prothocaragmatici" (*Gramm. Rhythmi*, 1468), "impressores librorum," "exsculptor librorum" (Jenson, 1471), "chalcographus" (1473; Hain, 13036), "magister artis impressoriae," "boeckprinter"; and during the 16th century we find them still frequently called "chalcotypus" and "chalcographus."

Types.

The types were at first designated more by negative than positive expressions. In 1468 they were called "caragma," later on "character" or "character," "archetipe notæ" (1473; Hain, 13036), "sculptoria archetyporum ars," "chalcotypa ars," "formæ," "artificiosissimæ imprimendorum librorum formæ." We soon hear also of the process and material by which they were produced. The *Grammatica* of 1468, published by Schoeffer, says that it was "cast" (sum fusus libellus). In 1471 "æneæ formulæ" are spoken of; and Bernardus Cenninus and his son say that they had printed the Virgil "expressis ante calibet characteribus et deinde fuis literis" (with letters first cut into steel and then cast). In 1473 Friedrich Creusner at Nuremberg says that he had "cut" (sculpsit) the work of Diogenes (Hain, 6192). Johan Zeiner of Ulm says in 1474 that he had perfected a book, not with the pen, but with letters of metal (stagneis characteribus). In 1474 Joh. Ph. de Lignamine speaks of "metallicæ formæ." In 1476 Husner of Strasburg represents the Nider as being printed with "letters cut of metal (litteris sculptis artificiali certe conatu ex ære)." Nicolas Jenson printed in 1480 with letters "cut and cast" (sculptis ac conflatis).

Word "typo-graphy."

The word *typographus* does not seem to occur before 1488, when it was used in the preface of P. Stephanus Dulcinius Scale to the *Astronomicum* of Manilius, printed in that year at Milan by Antonius Zarotus;¹ in 1498 Erasmus uses it in a letter (dated 13th Feb.) to Christianus, a Lübeck merchant;² and in 1517 Johan Schoeffer applies the word to himself in the colophon of the *Æneas Sylvius* published by him. But of the use of the word *typographia* no earlier instance is known than 1520, in which year Gerardus Noviomagus (=Geldenhaurius) in his *Lucubratiuncula de Batavorum Insula* (pref. to Nicol. Buscoducensis, dated 1520) says: "inventa Germanorum . . . bombardia videlicet, typographia, pyxis charactæ nautica;" and Johan Schott, a printer of Strasburg, in the *Geogr. Ptolem.* published by him, describes his grandfather, Johan Mentelin, as "primus typographiæ inventor." Gerardus, it may be added, borrowed the whole passage from Pet. Montanus (li. 1 *Adag.*, published a. 1504), who has *chalcographia* instead of *typo-*

graphia. Meerman indeed³ speaks of a use of the word *typographia* (or at least of *typographus*) earlier than 1520, and refers to the preface of Bernardinus Veronensis in the edition of Tibullus, Catullus, and Propertius published at Venice in 1493 by Symon Bevilacqua, "at least," Meerman adds, "as it (the preface) is read in the *Annal. Typogr.* of Maittaire, i. 560, 2d ed." But on page 560 Maittaire quotes the first two lines of Bernardinus's preface (till *dicit*) and then adds: "Græcis characteribus destitutus, typographus necesse habuit hiatus in commentario hic illic relinquere," which is evidently Maittaire's own remark, not that of Bernardinus. The present writer at least has been unable to find such a passage in the Tibullus.

Although the art of writing and that of block-printing both differ widely from printing with movable metal types, yet this last process seems to have been such a gradual transition from block-printing, and block-printing in its turn to have been such a natural outcome of the many trials that were probably made to produce books in some more expeditious manner than could be done with hand-writing, that a cursory glance at these two processes will not seem out of place, all the less as a discussion on the origin and progress of typography could hardly be understood without knowing the state of the literary development at the time that printing appeared.

The art of printing, *i.e.*, of impressing (by means of First certain forms and colours) figures, pictures, letters, words, attempts lines, whole pages, &c., on other objects, as also the art of engraving, which is inseparably connected with printing, existed long before the 15th century. Not to go back to remoter essays, there is reason to suppose that mediæval kings and princes (among others William the Conqueror) had their monograms cut on blocks of wood or metal in order to impress them on their charters. Such impressions from stamps are found instead of seals on charters of the 15th century. Manuscripts of the 12th century show initials which, on account of their uniformity, are believed to have been impressed by means of stamps or dies.⁴ But the idea of multiplying representations from one engraved plate or block or other form was unknown to the ancients, whereas it is predominant in what we call the art of block-printing, and especially in that of typography, in which the same types can be used again and again.

Block-printing and printing with movable types seem to have East been practised in China and Japan long before they were known in Asiatic Europe. It is said that in the year 175 the text of the Chinese printing. classics was cut upon tablets, which were erected outside the university, and that impressions were taken of them, some of which are said to be still in existence. Printing from wooden blocks can be traced as far back as the 6th century, when the founder of the Suy dynasty is said to have had the remains of the classical books engraved on wood, though it was not until the 10th century that printed books became common. In Japan the earliest example of block-printing dates from the period 764-770, when the empress Shiyau-toku, in pursuance of a vow, had a million small wooden toy pagodas made for distribution among the Buddhist temples and monasteries, each of which was to contain a dhâranî out of the Buddhist Scriptures entitled "Vimala nirbhasa Sâtra," printed on a slip of paper about 18 inches in length and 2 in width, which was rolled up and deposited in the body of the pagoda under the spire. In a journal of the period, under the year 987, the expression "printed" book (*suri-hon*) is found applied to a copy of the Buddhist canon brought back from China by a Buddhist priest. This, of course, must have been a Chinese edition; but the use of the term implies that printed books were already known in Japan. It is said that the Chinese printed with movable types (of clay) from the middle of the 11th century. The authorities of the British Museum exhibit as the earliest instance of Korean books printed with movable types a work printed in 1337. To the Koreans is attributed the invention of copper types in the beginning of the 15th century; and an inspection of books bearing dates of that

² *Opp.*, iii. col. 24.

period seems to show that they used such types, even if they did not invent them.¹

From such evidence as we have it would seem that Europe is not indebted to the Chinese or Japanese for the art of block-printing, nor for that of printing with movable types.

MS.
period.

In Europe, as late as the second half of the 14th century, every book (including school and prayer books), and every public and private document, proclamation, bull, letter, &c., was written by hand; all figures and pictures, even playing-cards and images of saints, were drawn with the pen or painted with a brush. In the 13th century there already existed a kind of book trade. The organization of universities as well as that of large ecclesiastical establishments was at that time incomplete, especially in Italy, France, and Germany, without a staff of scribes and transcribers (*scriptores*), illuminators, lenders, sellers, and custodians of books (*stationarii librorum, librarii*), and *pergamenerarii*, i.e., persons who prepared and sold the vellum or parchment required for books and documents. The books supplied were for the most part legal, theological, and educational, and are calculated to have amounted to above one hundred different works. As no book or document was approved unless it had some ornamented and illuminated initials or capital letters, there was no want of illuminators. The workmen scribes and transcribers were, perhaps without exception, calligraphers, and the illuminators for the most part artists. Beautifully written and richly illuminated manuscripts on vellum became objects of luxury which were eagerly bought and treasured up by princes and people of distinction. Burgundy of the 15th century, with its rich literature, its wealthy towns, its love for art, and its school of painting, was in this respect the centre of Europe, and the libraries of its dukes at Brussels, Bruges, Antwerp, Ghent, &c., contained more than three thousand beautifully illuminated MSS.

Classes
of writing.

In speaking of the writing of the manuscripts of the 15th and two preceding centuries, it is essential to distinguish, in each country, between at least four different classes of writing, and two of these must be again subdivided each into two classes. All these different kinds of writing were, in the first instance, taken as models for cutting such portions of text as were intended to illustrate and explain the figures in block-books, and afterwards as models for the types used in the printing of books and documents.

(1) The *book hand*, that is, the ordinary writing of legal, theological, and devotional books, was used by the official transcribers of the universities and churches. These men had received a more or less learned education, and consequently wrote or transcribed books with a certain pretence of understanding them and of being able to write with greater rapidity than the ordinary calligrapher. Hence their writing may be called (a) the *current* or *cursive book hand*, of which a good many illustrations may be found in Wilh. Schum, *Exempla Codicum Amplon. Erfurtensium*. Quite distinct from this current writing, and much clearer and more distinct, is (b) the *upright* or *set book hand*, which was employed by some writers who worked for universities and churches, and also by a good many who may be presumed to have worked in large cities and commercial towns for schools and the people in general without university connexion. (2) In the *church hand* (Gothic or black letter) were produced transcripts of the Bible, missals, psalters, and other works intended for use in churches and private places of worship. This writing we may again subdivide into two classes,—(a) the *ornamental* or *caligraphic* writing, found exclusively in books intended for use in churches or for the private use of wealthy and distinguished persons, and (b) the ordinary *upright* or *set church hand*, employed for less ornamental and less expensive books. (3) The *letter hand* may be said to be intermediate between the set literary book hand and the set literary church hand, and to differ but little from either. It was employed in all public documents of the nature of a letter. (4) The *court* or *charter hand* was used for charters, title-deeds, papal bulls, &c.

¹ See Ern. Satow, "On the Early Hist. of Printing in Japan," in *Trans. Asiatic Soc. of Japan*, x. 48 sq.; and Stan. Julien, "Documents sur l'Art d'Imprimer," &c., in *Journ. Asiat.*, 4^{me} ser., ix. 505.

Dypold Läber (Lauber), a teacher and transcriber at Hagenau in 15th-Germany, is known to have carried on a busy trade in manuscripts century just about the time of the invention of printing. His prospectuses, books, in handwriting of about the middle of the 15th century; announce written, that whatever books people wish to have, large or small, "geistlich oder weltlich, hübsch gemolt," are all to be found at Dypold Lauber's scribe. He had in stock *Gesta Romanorum*, mit den *Vignen gemolt*; poetical works (*Parcival, Tristan, Freidank*); romances of chivalry (*Der Wiltarn Ritter; Von einem Getruwen Ritter der sin eigen Hertze gab umb einer schönen Frowen willen; Der Ritter unter dem Zuber*); Biblical and legendary works (*A Rimed Bible; A Psalter, Latin and German; Episteln und Evangelien durch das Jor; Vita Christy; Das gantze Passional, winterteil und summerteil*); devotional books (*Bellial; Der Selen Trost; Der Rosenkrantz; Die zehn Gebot mit Glosen; Small Bette-Bücher*); and books for the people (*Gute bewehrte Artzen-Bücher; Gemolte Loss-Bücher, i.e., fortune-telling books; Schachtzabel gemolt*). The lower educational books consisted for the most part of the *Abececlaria*, containing the alphabet, the Lord's prayer, the creed, and one or two prayers; the *Donatus*, a short Latin grammar extracted from the work of Ælius Donatus, a Roman grammarian of the 4th century, and distinctly mentioned in a school ordinance of Bautzen of 1418; the *Doctrinale*, a Latin grammar in leonine verse, compiled by Alexander Gallus (or De Villa Dei), a minorite of Brittany of the 13th century; the *Summula Logica* of Petrus Hispanus (afterwards Pope John XXI.), used in the teaching of logic and dialectics; and Dionysius Cato's *Disticha de Moribus*, and its supplement called *Facetus*, with the *Floretus* of St Bernard, used in the teaching of morals. As helps to the clergy in their attempts to educate the lower classes, and as a means of assisting and promoting private devotion, there were picture books accompanied with an easy explanatory text, for the most part representations of the mystic relation between the Old and New Testaments (typology). Among these books the *Biblia Pauperum*² stands first. It represents pictorially the life and passion of Christ, and there exist MSS. of it as early as the 13th century, in some cases beautifully illuminated.³ A richly illuminated MS. of it, executed in the Netherlands c. 1400, is in the British Museum (press-mark, King's, 5), and also fragments of one of the 14th century (press-mark, 31,303). A remodelling and development of this work is the *Speculum Humanæ Salvationis*, a work in rhyme of the 14th century, which in forty-five chapters represents the Bible history interwoven with Mariolatry and legend. Of this work the Paris national library and arsenal library each possesses a MS. composed in 1324, whereas the British Museum has nine MSS. (six being illuminated) of the 14th and 15th centuries, written in the Netherlands, Germany, France, and England, one (press-mark, 16,578) bearing the distinct date 1379 and another (press-mark, Egerton, 878) that of 1486. A work of a similar nature is the *Apocalypsis*, of which at least two recensions with illustrations may be pointed out. One gives the text as we know it, with or without commentary, for which cf. Brit. Mus., 17,333 (French), 18,633 (French, but written in England), Reg. 2 D. xiii., and 22,493 (French),—all four early 14th century. Another is more a short history or biography of St John, but the illustrations follow those of the former work very closely; cf. Brit. Mus., 19,896 (15th century, German). It is this last recension which agrees with the block-book to be mentioned hereafter. Other devotional works are the *Arx Moriendi*, the *Antichrist*, and other works which will be found mentioned among the block-books.

Block-Printing or Xylography.

When all this writing, transcribing, illuminating, &c., Block-had reached their period of greatest development, the art printing, of printing from wooden blocks (block-printing, xylography) on silk, cloth, &c., vellum, and paper made its appearance in Europe. It seems to have been practised, so far as we have evidence, on cloth, &c., and vellum as early as the 12th century,⁴ and on paper as far back as the second half of the 14th century, while it was largely employed in the early part of the 15th in the production of (1) separate leaves (called *briefs*, from *breve*, scriptum), containing either a picture (*print*, *prent*, shortened from the Fr. *emprint*, *empreinte*, and already used by Chaucer, *C. T.*, 6186, six-text, D. 604, *printe*, *prente*, *preente*, and in other early English documents; also called in colloquial German *Helge*, *Helglein*, or *Halge*) or a piece of text, or both together;

² We find this title applied to at least three works,—(1) the well-known block-book, of which we speak below, (2) a treatise "in qua de vitis et virtutibus agitur," and (3) a work in rhyme by Alexander Gallus.

³ See Laib and Schwarz, *Biblia Pauperum*, Zurich, 1867.

⁴ Weigel, *Anfänge*, i. 10.

and of (2) whole block-books, sometimes consisting of half picture and half text, or wholly of text, or altogether of picture.¹ It is, however, certain that about 1400 xylography was known all over Germany, Flanders, and Holland.

In these blocks, as in wood-engraving now, the lines to be printed were in relief. The block, after the picture or the text had been engraved upon it, was first thoroughly wetted with a thin, watery, pale brown material, much resembling distemper; then a sheet of damp paper was laid upon it, and the back of the paper was carefully rubbed with some kind of dabber or burnisher, usually called a *frotton*, till an impression from the ridges of the carved block had been transferred to the paper. In this fashion a sheet could only be printed on one side (anopisthographic); and in some copies of block-books we find the sides on which there is no printing pasted together so as to give the work the appearance of an ordinary book. There are only a few block-books which do not possess this characteristic, as the *Legend of St Servatius* in the royal library of Brussels, *Das Zeitglocklein* in the Bamberg library (cf. Falkenstein, p. 49), *Das geistlich und weltlich Rom* at Althorp and Gotha (cf. Falkenstein, p. 46); but these belong to the end of the 15th century, and therefore to a later period than the ordinary block-books. Consequently, if a man wanted to set up as a printer of briefs or books, he needed no apparatus but a set of wood-blocks and a rubber.

Block-printers.

Formerly it was the general opinion that playing-cards had been the first products of xylography; but the earliest that have been preserved to us are done by hand, while the printed ones date from the 15th century, therefore from a period in which woodcuts were already used for other purposes. It is believed that some of the wood engravings and block-books were printed in monasteries. In a necrology of the Franciscan monastery at Nördlingen, which comes down to the beginning of the 15th century, this entry occurs: "VII. Id. Augusti, obiit Frater h. Luger, laycus, optimus incisor lignorum"; and on some of the engravings we find the arms of certain monasteries, which may, however, merely mean that they were printed for, not in, those monasteries. The registers of Ulm mention several wood-engravers (*formschneider*),—in 1398 a certain Ulrich; in 1441 Heinrich Peter von Erolzheim, Joerg, and another Heinrich; in 1442 Ulrich and Lienhart; in 1447 Claus (Nicolas), Stoffel (Christopher), and Johann; in 1455 Wilhelm; in 1461 Meister Ulrich, &c. In a register of taxes of Nördlingen we find from 1428 to 1452 a certain Wilhelm Kegerler mentioned as *brief-trucker*; in 1453 his widow is called *alt brieftruckerin*; and in 1461 his brother Wilhelm is registered for the same craft. At Mainz there was a printer, Henne Cruse, in 1440. At Nuremberg we find in 1449 Hans, a *formschneider*, while his son Junghans exercised the same industry from 1472 to 1490. Hans von Pfedersheim printed at Frankfort in 1459, and Peter Schott at Strasburg in 1464. A certain George Glockendon exercised the same trade at Nuremberg till 1474, when he died, being succeeded by a son and afterwards by a grandson. In Flanders a Jan de Printere was established at Antwerp in 1417; and printers and wood engravers (*houtte bild-snyters*) worked there in 1442 (*Privileges of the Corporation of St Luke* at Antwerp). At Bruges printers and beeldmakers (makers, engravers of images) were enumerated in 1454 among the members of the fraternity of St John the Evangelist. The printers of playing cards seem to have constituted a separate class. These entries show that about the middle of the 15th century there were men who exercised the art of wood-engraving and printing as a trade or craft. It seems also certain that wealthy persons and religious institutions were wont to possess sets of blocks, and, when occasion arose, they printed a set of sheets for presentation to a friend, or in the case of monasteries for sale to the passing pilgrim. A printer of briefs or block-books had no need to serve an apprenticeship; any neat-handed man could print for himself. We learn from the inventory of the possessions of Jean de Hinsberg, bishop of Liège (1419-1455), and his sister, a nun in the convent of Bethany, near Mechlin, that they possessed "unum instrumentum ad imprimendas scripturas et ymagines," and "novem printe ligneæ ad imprimendas ymagines cum quatuordecim aliis lapideis printis." These entries would seem to indicate that people purchased engraved blocks of wood or of stone from the woodcutter rather than books from a printer.

Early dated wood-engravings.

The earliest dated woodcut that we know of is the St Christopher of 1423, preserved in the library of Lord Spencer at Althorp. The Mary engraving, which is preserved at Brussels and apparently bears the date mcccxxviii., is now declared to be of 1468, the date having been falsified. The next date after that of the St Christopher is 1437, found on a woodcut preserved in the imperial library at Vienna. It was discovered in 1779 in the monastery of St Blaise in the Black Forest, and represents the martyrdom of St Sebastian, with fourteen lines of text. The date, however, is said by others to refer to a concession of indulgences. A woodcut, preserved in the library at Vienna, which represents St Nicolas de Tolentino, has the date 1440, but written in by hand; as the saint was canonized

in that year, it may refer to that event. Another in the Weigel collection representing the bearing of the cross, St Dorothea and St Alexis, has the date 1443, also written in by hand, though the woodcut is considered to belong to that period. These are the only known wood-engravings with dates anterior to the second half of the 15th century. But there exist a good many woodcuts which, from the style of the engraving, are presumed to be of an earlier date, and to have been printed partly in the fourteenth and partly in the first half of the 15th century. J. D. Passavant² enumerates twenty-seven, all of German origin and preserved in various libraries in Germany, while in the *Collectio Weigeliana* (vol. i.) no fewer than 154 are recorded, some of which are to be ascribed to the Netherlands. We know of the existence of at least five engravings which may be ascribed to the Netherlands:—(1) representing the Virgin Mary, with Dutch inscriptions, in the museum at Berlin; (2) representing the Virgin Mary spoken of above, in the library at Brussels; (3) representing St Anthony and St Sebastian, in the Weigel collection; (4) a St Hubert and St Eustatius, in the royal library at Brussels; (5) representing the Child Jesus, in the library at Berlin; (6) the Mass of St Gregory, with indulgence, in the Weigel collection (cf. i. 195).

Of block-books of probable German origin the following are known:—

(1) The *Apocalypsis*, or *Historia S. Johannis Evangelistæ ejusque Visiones Apocalypticæ* (Germ. *Das Buch der heymlichen Offenbarungen Sanct Johans*). Of this work six or seven editions are said to exist, each containing forty-eight (the 2d and 3d edition fifty) illustrations, on as many anopisthographic leaves, which seem to have been divided into three quires of eight sheets each. The first edition alone is without signatures.

(2) *Ars Moriendi*. Of this work some authors think that there are early German editions, among others that spoken of below as the 2d Dutch edition. Certainly German is the edition of Hans Sporer of Nuremberg, 1473, in the public library at Zwickau, of another by Ludwig zu Ulm, in the Paris national library, and of that described in *Collectio Weigel*. (ii. 16), where also other, but opisthographic, editions are described.

(3) *Ars Memorandi*; thirty leaves, folio, printed on one side, fifteen leaves being letter-press and fifteen plates.

(4) *Salve Regina*, bears the name of its engraver, Lienhart czu Regenspuck. It is composed of sixteen leaves; two leaves (signature a) are wanting in the only copy known of it, which was in the Weigel collection (ii. 103).

(5) *Vita Christi*; thirty-two leaves, sm. 8vo. Two copies in the Paris library (Sotheby, ii. 143).

(6) *The Ten Commandments for Unlearned People* (*Die zehn Bott für die ungelernete Leut*). Ten leaves are preserved in the library at Heidelberg bound up with a manuscript (No. 438).³

(7) *The Passion of Our Lord*; sixteen leaves, in the Weigel collection (Sotheby, ii. 141).

(8) *The Antichrist* (*Der Eundchrist*); twenty-six leaves, small folio (Sotheby, ii. 38; Weigel, ii. 111). Copies, Lord Spencer and coll. Weig.

(9) *The Fifteen Signs of the Last Judgment*; twelve engravings, usually bound up with the engravings of *The Antichrist* (Sotheby, ii. 42). Copy, Lord Spencer. There is also an edition published at Nuremberg in 1472 by Junghannss Priffinaler.

(10) *Symbolum Apostolicum*; small quarto, seven leaves printed on one side only, and containing twelve woodcuts with German inscriptions. The only copy of it known is preserved in the library of Munich (Sotheby, ii. 148).

(11) *The Legend of St Meinrad*; forty-eight leaves. The only copy known is preserved in the Munich library (Sotheby, ii. 150).

(12) *The Acht Schallheiten*, of which eight leaves were in the Weigel collection (i. 112; Sotheby, ii. 154).

(13) *The Fable of the Sick Lion*; twelve leaves, preserved in the library at Heidelberg (No. 438; see Sotheby, ii. 159, pl. lxxxvi.).

(14) *Defensorium Inviolatæ Virginitatis b. Mariæ Virginis*; sixteen leaves fol. The unique copy is in the British Museum. On the first leaf are the initials of the printer F[r]iedrich W[altheren] and the date 1470 (Sotheby, ii. p. 63).

(15) The same work, twenty-seven leaves, large folio, with the imprint "Johannes eysehüt impressor Anno ab incarnacōis dñice M^o quadringentesimo septuagesimo j^o" (cf. Sotheby, ii. 72). Copy in the British Museum.

(16) *The Dance of Death* (*Dance Macabre; Der Doten Dantz*); twenty-seven leaves (Sotheby, ii. 156).

(17) *Die Kunst Ciromantia* of Dr Johan Hartlieb (Sotheby, ii. 84).

(18) *Der Beichtspiegel or Confessionale*; eight engravings (Sotheby, ii. 145). Copy in the royal library at The Hague.

(19) *The Apostles' Creed*; seven leaves, folio. Copy at Wolfenbüttel.

(20) *The Credo*, in German; twelve leaves, quarto. Copy in the royal library at Munich.

¹ We have also evidence that sometimes the picture or figures were printed from blocks, space being reserved for the text, to be added afterwards by hand (see Bernard, *Origine*, i. 102).

² *Le Peintre-Graveur*, i. 27 sq.

³ See Joh. Geffcken, *Der Bilderstechismus des 15 Jahrh.*, Leipsic, 1855, quarto; Sotheby, ii. 160.

Of
Nether-
landish
origin.

Propugnaculæ, seu Turris Sapientiæ; one sheet, plano, Brit. Mus. (Sotheby, ii. 184).

Block-books of Netherlandish origin are:—

- (1) *Biblia Pauperum*; forty leaves (each bearing a signature; *a* to *v*, *a*-to-*v*). As many as seven editions have been distinguished by Sotheby (i. 43; see also Holtrop, *Monum. Typ.*, p. 3).
- (2) *Ars Moriendi*;¹ twenty-four leaves, small folio, thirteen containing text, eleven plates (see Sotheby, i. 69; Holtrop, p. 8).
- (3) *Canticum Canticorum, Historia seu Providentia B. Virginis, Mariæ ex Cantico Canticorum*; sixteen leaves, in fol. (Sotheby, i. 77; Holtrop, p. 6).
- (4) *Liber Regum, seu Historia Davidis*; twenty leaves, folio (Sotheby, i. 120b). Some consider this to be a German work.
- (5) *Exercitium super Pater Noster*, by Henricus de Pomerio; ten leaves, small folio (Sotheby, ii. 137; Holtrop, p. 10).²
- (6) *Temptationes Demonis Temptantis Hominem de Septem Peccatis Mortalibus*; a single large folio leaf printed on one side. Two copies, one in British Museum, the other in the library at Wolfenbüttel.
- (7) *Vita Christi*, or the *Life and Passion of Christ*; thirty-six cuts, originally printed in a press on six anopisthographic leaves, 8vo. In the library at Erlangen (see Campbell, *Annales*, 746).
- (8) *Historia Sanctæ Crucis*; a fragment of one leaf (with signature *g*), preserved in the Weigel collection (ii. 92), which seems to be a proof-sheet only.
- (9) *Alphabet in figures* (Holtrop, p. 11; Sotheby, i. 122).³
- (10) *Pomerium Spirituale*, by Henricus de Pomerio or Henry Bogaert; twelve leaves, having twelve woodcuts accompanied by MS. text, in the library at Brussels (Holtrop, *Mon. Typ.*, p. 9). It bears the date 1440 in two places; but some contend that this refers to the date when the book was written,⁴ not when the engravings were printed.

Besides the works of Sotheby, Holtrop, and Weigel, already quoted, consult W. M. Conway, *The Woodcutters of the Netherlands in the 15th Century*, Cambridge, 1884; Heineken, *Idee Générale*, Leipsic, 1771; J. Ph. Berjeau, *Facsimiles of the Biblia Pauperum, Canticum Canticorum, Speculum*, London, 1859-1861; and Id., *Catal. Illustré des Livres Xylogr.*, London, 1865.

Early Printing at Mainz.

When we, for the moment, leave out of sight the question as to when, where, and by whom the art of printing with movable metal types was invented, and take our stand on well-authenticated dates in such printed documents as have been preserved to us, we find that the first printed date, 1454, occurs in two different editions of the same letters of indulgence issued in that year by Pope Nicholas V. in behalf of the kingdom of Cyprus.

These two editions are distinguished respectively as the 31-line and the 30-line indulgence. The former, of which three different issues with the printed date mccccliii., and a fourth with the printed date mcccclv., are known to exist, claims priority⁵ from a chronological point of view over the latter, of which one issue with the printed date mccccliii., and two issues with the printed date mcccclv., are known to exist, because one of the sold copies that has been preserved was issued at Erfurt on 15th November 1454, whereas of the 30-line indulgence the earliest sold copy that has as yet come down to us was issued at Cologne on 27th February 1455, though it distinctly has the printed date mccccliii., but altered with the pen to mcccclv. In the 31-line indulgence occur (1) a large church type usually regarded as identical with that of the 36-line Bible, and used for the rubrics of the absolutions, for the word with which the document commences, and for the Christian name of the pope's legate; (2) a smaller text or brief type, which was afterwards very closely imitated, if not actually used, at Eltville, in printing the 1472 edition of the *Vocabularius ex quo* and an edition of the *Summa de Articulis Fidei* of Thomas Aquinas; (3) a large initial V and two large initials M, which differ from each other. In the 30-line indulgence occur (1) a large church type, which is used as in the 31-line indulgence, and is usually regarded as identical with that of the 42-line Bible; (2) a smaller text or brief type, of which as yet no further trace has been found; (3) a large initial U, and two large initials M, which differ from each other, the first being identical with the initial M of the second absolution of a 33-line indulgence printed by Peter Schoeffer in 1439 for "Raymundus Peyraudi, archidiaconus Alnsiensis in

ecclesia Xanton," who issued it at the order of Pope Innocent VIII., "pro tuicione orthodoxe fidei contra Turchos." These two different editions are usually regarded as having been printed at Mainz; and, so long as there is no evidence to the contrary, we may printing, assume that such was really the fact. But we must at the same time conclude that about November 1454 there were at least two rival printers at work there,—(1) the printer of the 31-line indulgence, whose name has not yet transpired, but who may have been Johan Gutenberg, perhaps subsidized by Johan Fust; (2) the printer of the 30-line indulgence, who was no doubt Peter (Schoeffer) de Gernssheym, on account of the connexion of this indulgence with that of 1489, which was unquestionably printed by him. Latterly four written copies of the same indulgence have been found, which respectively bear the dates,—Frankfurt, 10th April 1454 (in the possession of Herr Lais, Wiesbaden); Frankfurt, 11th April 1454 (Frankfurt archives); 11th July 1454 (place unknown; Darmstadt archives); Lübeck, 6th October 1454. As their dates precede by a few weeks only the earliest known printed date (15th November 1454), they mark, perhaps, the exact time when printing made its appearance at Mainz in an already advanced state of perfection.

In following up the basis afforded by the above indulgences we Early may give a short chronological view of the early printing at Mainz, typesand so far as it is at present known, referring for minute details to J. H. books at Hessels, *Gutenberg: Was he the Inventor of Printing?* 1882, p. Mainz. 150 sq.

Types 1 (large church type) and 2 (smaller brief type), used by an unknown printer, 1454.

- (i.) 31-line indulgence; three different issues (A, B, C), with the printed year mccccliii., and one issue (D) with the printed year mcccclv. All printed on vellum. Of issues A and B no sold copies have yet come to light. Three unsold copies of each are preserved at (1) Brunswick, (2) Wolfenbüttel, and (3) Hanover (Culemann). Of issue C eight sold copies are known to exist in various libraries, with dates from Nov. 15 1454 to Apr. 30 1455. Also four unsold copies have been discovered. Of issue D ten sold copies with dates from Mar. 7 1455 to Apr. 30 1455 and four unsold copies are known.

TYPE 1, continued; for type 2 see below.

- (ii.) *Manung wider die Durke*. An almanac for Jan. 1455, in 4to, 5 leaves, 20 and 21 uneven lines. The only copy known was discovered at Augsburg, and is now in the Munich library.
- (iii.) *Conjunctiones et Oppositiones Solis et Lunæ*. A calendar for 1457, a broadside sheet, printed on one side. The upper half of the only copy known was discovered at Mainz, and is now in the Paris library.
- (iv.) *Der Cisiannus* (not Cislannus) *zu Deutsche*. A broadside sheet, printed on one side, 36 lines, besides separate head-line. The Tross copy, mentioned in Suppl. to Brunet's *Manuel* (1878, s.v. "Cislannus"), was bought in 1870 for the Cambridge university library.
- (v.) and (vi.) *Donatus*. Two different editions of 14(?) leaves each, 27 lines (B. Mus., C. 18 a 1, Nos. 2 and 5).
- (vii.) *Donatus* of 30 lines, 12 (?) leaves; a fragment of the 8th (?) in the Mainz library.
- (viii.) 36-line Bible. 2 vols. fol., 882 leaves, with 2 columns of 36 lines each on a page. Some bibliographers call this the Pfister Bible, assuming that Pfister printed it. The Paris library possesses a paper copy, and also a separate copy of the last leaf, which bears the MS. date 1461. Other copies exist in

Lord Spencer's library, in the Brit. Mus., at Jena, Leipsic, Antwerp, &c.

Types 3 (large church type) and 4 (smaller brief type), used by Peter Schoeffer de Gernssheym, 1454-1455.

- (i.) 30-line indulgence; one issue (A) with the printed year mccccliii., and two issues (B, C) with the printed year mcccclv. All printed on vellum. Of issue A only one copy has been discovered, now in Lord Spencer's library. It was sold at Cologne on Feb. 27 1455, the printed date mccccliii., having been altered with the pen to mcccclv. Of issue B two sold copies, with dates Apr. 11 and 29 1455, are in the Berlin library and the Brit. Mus. Of issue C two sold copies, with dates Feb. 22 and Apr. 24 1455, are at Hanover (Culemann) and Wolfenbüttel. An unsold copy is at Hanover (Culemann).

TYPE 3, continued (till about 1457); of type 4 no further trace is found.

- (ii.) *Donatus* of 24, 25, or 26 lines, 24 (?) leaves; one leaf (the 8th or 9th ?) in the Mainz library.
- (iii.) *Donatus* of 32 lines, 14 (?) leaves, the 10th (?) in the Mainz library.
- (iv.) *Donatus* of 38 lines, two leaves in the Paris library.
- (v.) *Donatus* of 35 lines, folio; printed, according to the colophon, "per Petrum de Gernssheym, in urbe Moguntina cum suis capitalibus."
- (vi.) 42-line Bible (also called *Mazarine Bible*), printed before Aug. 15 1456, as the binder of the paper copy in the Paris library states that he finished its rubrication on that day. 2 vols. fol., 641 leaves of 2 columns of 42 lines each, except that in some copies the columns of pp. 1-9 contain 40 lines only, while the 10th page has 2 columns of 41 lines each, though the difference in the number of lines makes no difference in the space which they occupy.⁷
- (vii.) 42-line *Cantica ad Matutinas*. The first and only leaf known is in the Paris library. It is printed on vellum, and corresponds in every respect to the 42-line Bible, having double columns, 42 lines, &c.

The above four types and the books printed with them (besides a few others printed by Albrecht Pfister at Bamberg) are the only ones that stand in close connexion with the question regarding the introduction, or the possible invention, of printing at Mainz. It has been pointed out above that one of the initial M's of the 30-line indulgence of 1454 occurs again in an indulgence of 1489, printed by Schoeffer; hence types 3 and 4 and the books printed with them must be ascribed to this printer, in spite of the fact that the capital P found in the indulgence does not seem to occur again in the 42-line Bible. No further trace of the brief type 4 has yet been found, and perhaps Schoeffer melted it down for his other types. As Schoeffer, in the colophon of the *Donatus* (v.) which bears his

⁶ See Hessels, *Gutenberg*, p. 180; and Bernard, *Origine*, ii. 81.

⁷ For other copies, see Bernard, *Origine*, i. 164, 177-192; and Hessels, *Gutenberg*, 170.

¹ Heineken enumerates six editions, of which one has inscriptions in German. See also an article by Guichard, in *Bull. du Bibliophile*, Paris, 1841.

² See also W. M. Conway, *Notes on the Exercitium super Pater Noster*, 1887.

³ There is one copy in the British Museum and another in the library at Basel, this last having the date 1464 engraved on the letter A, which is mutilated in the former. A similar alphabet preserved at Dresden seems to be a copy made in Germany.

⁴ Mr. W. M. Conway is of a different opinion; see *Notes on Exercitium*. Dumortier testifies to having seen another copy unaccompanied by MS. ("Notes sur l'imprimerie," in *Bull. Acad. Roy. de Belg.*, vol. viii., 1841).

⁵ No inferences can be drawn from this priority, as it merely rests on the date of a sold copy that has come to light.

name alone, says that it was printed "cum suis capitalibus," and as these capitals gradually disappear after 1459 and the type of the 42-line Bible is no longer found after 1456, we must presume that the seven incunabula mentioned above were printed by Peter Schoeffer alone before he entered (in 1457) into partnership with Johan Fust.¹

There is no such certainty as regards types 1 and 2 and the books printed with them. If the 31-line indulgence may be assumed to have been printed at Mainz, its printer was in all probability Johan Gutenberg, though it would seem from a lawsuit of 1455 (see p. 690 below) between him and Fust that in that year Gutenberg had not yet printed anything, and in 1454 (1455) Fust evidently called him to account for not having produced anything. Certain circumstances point to Albrecht Pfister as the printer of the eight incunabula in the left-hand column. First, he undoubtedly printed with type 1 in that city as early as 1461, for on 14th February of that year he issued in that type an edition of Boner's *Edelstein* (88 leaves, fol., with wood engravings), and printed with the same type at least eight other works,² one of which was issued in 1462, the seven others without a date. Secondly, most of the copies of the 36-line Bible were at one time or another preserved in the libraries of Bavaria, and a great number of fragments have been discovered in monasteries in that country, even in a register of the abbey of St Michael at Bamberg of the year 1460. Thirdly, a transfer of type from Gutenberg to Pfister is contrary to all analogy in the infancy of printing, when every printer started with a type of his own making. But, as there is no direct evidence as to who really possessed types 1 and 2 before 1460, we have not felt justified in assigning the 31-line indulgence and the other seven incunabula (including the 36-line Bible) to Pfister.

The
Catholi-
con type.

It is alleged that, in consequence of the lawsuit between Gutenberg and Fust, the former was deprived of all tools, &c., which he had made, or is supposed to have made, with the money which the latter had advanced to him, and that afterwards a certain Dr Homery or Humery, a syndic of Mainz, lent him fresh money to enable him to establish another printing office. This allegation is made on the strength of a letter of obligation (of 26th February 1468), given by Dr Homery to Adolph, the archbishop of Mainz, by which he acknowledges to have received from the said archbishop "several forms, letters, instruments, implements, and other things belonging to the work of printing, which Johan Gutenberg had left after his death, and which had belonged and still did belong to him (Dr Homery)." It is presumed that with these types, which we may call the Mainz type No. 5, Gutenberg printed (i.) Joannes de Balbis, *Catholicon*, 1460, 373 leaves, folio, 2 columns of 66 lines each, copies of which exist in the Cambridge university library, three in the British Museum, two in the Paris library, in Lord Spencer's library, in the Wolfenbüttel and Mainz libraries, &c.; (ii.) Matthæus de Cracovia, *Tractatus Rationis*, 22 leaves, 4to, 30 lines, three copies of which are in the British Museum, one at Althorp, one in the Cambridge library, two in the Paris library, &c.; (iii. and iv.) Thomas Aquinas, *Summa de Articulis Fidei*, two editions in 4to, the first of 13 leaves and 34 lines,—two copies of which are in the British Museum, one in Lord Spencer's, the Cambridge library, &c.—and the second of 12 leaves and 36 lines,—copies in the British Museum and the Paris library; and (v.) indulgence of 1461 of 15 lines.

On 18th January 1465 Adolph II., archbishop of Mainz, appointed "Johan Gudenberg, on account of his grateful and willing service, his servant and courtier (*diener und hofgesind*) for life, promising to supply him with clothing and each year 20 'malter' of corn and 2 'fuder' of wine." It has always been inferred from this that Gutenberg had quitted Mainz and gone to Eltville (Eltfeld) to reside at the archbishop's court, and that, his dignity as courtier preventing him from printing himself, he passed the *Catholicon* types on to Henry Bechtermuncze at Eltville. But recent researches have shown that Gutenberg remained at Mainz till his death in 1468. We certainly find in 1467 the *Catholicon* type with some additions (already found in the indulgence of 1461) at Eltville near Mainz, in the hands of Henry and Nicholas Bechtermuncze and Wigandus Spyes de Orthenberg, who finished on 4th November of that year (vi.) *Vocabularius ex quo* (a Latin-German vocabulary) in 4to, 166 leaves, 35 lines, the only known copy of which is in the Paris library, and (vii.) *Vocabularius ex quo*, second edition, with colophon dated 5th June 1469, 4to, 165 leaves, 35 lines, copies of which exist in Lord Spencer's library, at Blenheim, and in the Paris library. Now it is asked how the Bechtermunczes could have been using the *Catholicon* type in 1467, if we assume that it was this type to which Homery refers in his letter of obligation as being in his possession. Some, therefore, conclude that the *Catholicon* and the four other works in the same type were printed at Mainz by Henry Bechtermuncze, who may afterwards have transferred his printing office to Eltville. In that case it is difficult to see what type Homery could refer to, unless it were type 2, a close imitation of which, if not the actual type, was used by Nicholas

Bechtermuncze at Eltville in printing (12th March 1472) a third edition of the *Vocabularius ex quo*, 166 leaves, 35 lines, copies of which are preserved in the Paris and Hamburg libraries, and an edition of Thomas Aquinas, *Summa de Articulis Fidei*, 12 leaves, 35 lines (Munich library).

It is necessary to point out that for nearly seventy years eight books—(1) *Prognostication* or *Calendar*; (2) Hermann de Saldis, *Speculum Sacerdotum*; (3) *Tractatus de Celebratione Missarum*; (4) a work in German treating of the necessity of councils; (5) *Dialogus inter Hugonem Cathonem et Oliverium super Libertate Ecclesiastica*; (6) Sifridus de Arena, *Determinatio Duarum Quæstionum*; (7) Id., *Responsio ad Quatuor Quæstiones*; (8) *Klagspiegel*, or *New geuteschicht Rechtbuch*—have been ascribed to Gutenberg on the strength (a) of the date 1460, which was said to be found in the *Prognostication* in the Darmstadt library, and (b) of a so-called rubrication alleged to be in a copy of the *Tractatus de Celebratione Missarum*, in which "Johannes dictus a bono monte" and Johannes Numeister are represented as offering this work on 19th June 1463 to the Carthusians at Mainz. But the date in the *Prognostication* has been falsified from 1482 into 1460, and the rubrication in the *Tractatus* is a forgery.³ The eight books are now considered to have been printed by Erhard Reuwich.

When we set aside the above works, there is no further difficulty as regards the history of Mainz printing. Fust and Schoeffer worked together from 1457 to 1466, starting in August 1457 with an edition of the *Psalterium*, printed in large missal types, which, as far as we know, is the first printed book which bears a date, besides the place where it was printed and the name of the printers. It was reprinted with the same types in 1459 (the second printed book with date, place, and name of printer), in 1480, and in 1502 (the last work of Schoeffer, who had manufactured its types). In 1459 Fust and Schoeffer also published Gul. Durantus, *Rationale Divinorum Officiorum*, with the small type (usually called Durandus type) with which they continued to print long afterwards. In 1460 they published the *Constitutiones* of Pope Clement V., the text printed in a type (Clement type) about a third larger than the Durandus. This type was, however, in existence in 1459, as the colophon of the Durantus is printed with it.⁴

Spread of Typography.

Having explained the early printing of Mainz, in so far as it bears upon the controversy (see below) as to where and by whom of type the art of printing was invented, we can follow its spread to other graphy countries. After Mainz it was first established in 1460 at Strasbourg, where the first printers were,—1. Johann Mentelin, who completed a Latin Bible in that year, according to a rubrication in a copy at Freiburg in the Breisgau; 2. Adolph Rusch de Ingulien, who is presumed to be the printer of the undated books with a singularly-shaped R,⁵ c. 1464; 3. Henricus Eggestein, 1471; 4. George Husner; 5. Martin Flach, &c. In 1461 at Bamberg, where the first printer was Albrecht Pfister, who in that year published Boner's *Edelstein*, though it is still doubtful whether he did not print earlier (see above); 2. Joh. Sensenschmidt, c. 1480. 1465 at Subiaco; first and only printers Conrad Sweynheym and Arnold Pannarts, who completed in that year an edition of Cicero, *De Oratore*, and Lactantius, and removed to Rome in 1467. 1466 at Cologne, the printers being—1. Ulrich Zell, who published in that year Chrysostom, *Super Psalmo Quinquagesimo Liber Primus*, though it is presumed that he printed in 1463; 2. Arnold Ther Hoernen, 1470; 3. Johannes Koelhoff of Lübeck, 1470, who printed the *Cologne Chronicle* in 1499; 4. Nicolaus Götz, 1474; 5. Goiswinus Gops, 1475; 6. Petrus de Olpe, 1476 (not 1470); 7. Conradus Winter of Homburg, 1476; 8. Joh. Guldenschaaf, 1477; 9. Henricus Quentel, 1479, &c.⁶ 1467 at Eltville; first printers Nicolas and Henry Bechtermuncze and Wygandus Spyes de Orthenberg, who completed in that year a *Vocabularius ex quo*. 1467 at Rome; first printers Conrad Sweynheym and Arnold Pannarts from Subiaco, who published an edition of Cicero's *Epistolæ ad Familiares*, and Ulrich Hahn or Udalricus Gallus, who issued on 31st December 1467 Turrecremata's *Meditationes*. 1468 at Augsburg; first printer Günther Zainer or Zeyner. Same year at Basel; first printer Berthold Rot of Hanau. Same year at Marienthal; Brothers of the Common Life. 1469 at Venice; printers,—1. Johannes of Spires; 2. his brother Vindelinus of Spires; 3. Christopher Valdarfer; 4. Nicolas Jensen, &c. The further spread of typography is indicated by the following data:—1470 at Nuremberg (Johan Sensenschmidt, Friedr. Creusner, Anton Koberger, &c.), Berona or Beromünster in Switzerland (Helyas Helye alias De Llonffen), Foligno (Emilianus de Orfinis and Johannes Numeister), Trevi (Johann Reynard), Savigliano

³ See Hessels, *Gutenberg*, pp. 107-114.

⁴ See further Bernard, *Origine de l'imprimerie*, i. 216 sq.

⁵ M. Philippe, *Origine de l'imprimerie à Paris*, p. 219, mentions two books printed in this type, which contain manuscript notes to the effect that they were purchased in 1464 and 1467, so that Ingulien should be placed before Eggestein.

⁶ Johan Veldener, who is said to have printed at Cologne, was never established there, but at Louvain (1473-77), Utrecht (1478-81), and Culemborg or Kulenburg (1483-84); see Holtrop, *Mon. Typ.*, pp. 42, 47, 109.

² See Hessels, *Gutenberg*, p. 161 sq.

(Hans Glim), Paris (first printers the three partners Ulrich Gering, Michael Friburger, Martin Krantz); 1471 at Spire, Bologna, Ferrara, Florence, Milan, Naples, Pavia, Treviso, Savignano (?); 1472 at Esslingen, Cremona, Mantua, Padua, Brescia, Parma, Monreale (Mondovi), Fivizzano, Verona, Iesi (?), St Ursino (?); 1473 at Lauringen, Ulm (perhaps as early as 1469), Merseburg, Alost, Utrecht, Lyons, Messina, Buda; 1474 at Louvain, Genoa, Como, Savona, Turin, Vicenza, Valencia (?); 1475 at Lübeck, Breslau, Blaubeuren, Burgdorf, Trent, Cracow (?), Modena, Reggio (in Calabria), Cagli, Caselle or Casale, Pieve (Pieve) di Sacco, Perugia, Piacenza, Saragossa; 1476 at Rostock, Bruges, Brussels, Angers, Toulouse, Poliano (Pogliano); 1477 at Reichenstein, Deventer, Gouda, Delft, Westminster, Lucca, Ascoli, Palermo, Seville; 1478 at Oxford, St Maartensdyk, Colle, Schussenried (in Württemberg), Eichstätt, Geneva, Vienne, Trogen (?), Chablais, Cosenza, Prague, Barcelona; 1479 at Erfurt, Würzburg, Nimeguen, Zwolle, Poitiers, Toscolano, Pinerolo, Novi, Lerida, Segorbe; 1480 at London, St Albans (or in 1479), Oudenarde, Hasselt, Reggio (in Modena), Salamanca, Toledo, Nonantola, Friuli (?), Caen; 1481 at Passau, Leipsic, Magdeburg, Treves, Urach, Casale di San Vaso, Saluzzo, Albi, Rougemont (?); 1482 at Reutlingen, Memmingen, Metz, Pisa, Aquila, Antwerp, Promentour, Zamora, Odense; 1483 at Leyden, Küllenburg (Culenburg), Ghent, Chartres, Chalons-sur-Marne (?), Troyes, Gerona, Stockholm; 1484 at Bois-le-Duc, Siena, Udine, Soucino, Winterberg, Klosterneuburg, Rennes, Loudéac; 1485 at Heidelberg, Ratisbon, Pescia, Vercelli, Tréguier or Lantreguet, Salins, Burgos, Palma, Xeres; 1486 at Münster, Stuttgart, Chiavasco, Voghera, Casal Maggiore, Abbeville, Brünn, Schleswig; 1487 at Ingolstadt, Gaeta, Rouen, Murcia; 1488 at Stendal, Viterbo, Gradisca, Besançon, Constantinople; 1489 at Hagenau, San Cucufat (near Barcelona), Coria, Pamplona, Tolosa, Lisbon; 1490 at Orleans, Grenoble, Dôle; 1491 at Hamburg, Nozzano, Goupillières, Angoulême, Dijon, Lantenac; 1492 at Zinna, Valladolid, Leiria; 1493 at Lüneburg, Cagliari, Freiburg (in Breisgau), Urbino, Acqui; 1494 at Oppenheim, Monterey, Braga; 1495 at Freisingen, Freiberg, Scandiano, Forlì, Limoges, Schoonhoven (monastery Den Hem), Wadstena, Cettinje; 1496 at Offenburg, Provins, Granada; 1497 at Munich, Barco, Carmagnola, Avignon; 1498 at Tübingen, Perigneux, Schiedam, Tarragona; 1499 at Montserrat, Madrid; 1500 at Olmütz, Pforzheim, Sursée, Perpignan, Valenciennes, Jaen. Printing was introduced into Scotland in 1505 by the establishment of Andrew Millar at Edinburgh,¹ and into Ireland, at Dublin, in 1551. As for non-European countries and towns, printing was established in Mexico in 1544, at Goa about 1550, at Tranquebar in 1569, Terceira in the Azores 1583, Lima 1585, Manila and Macao (China) 1590, in Hayti in the beginning of the 17th century, at Puebla in 1612, Cambridge (Mass.) 1638, Batavia 1668, Tiflis 1701, German-town 1735, Ceylon 1737, Halifax (Nova Scotia) 1766, Madras 1772, Calcutta 1778, Buenos Ayres 1789, Bombay 1792, in Egypt (at Alexandria, Cairo, and Gizeh) in 1798, at Sydney 1802, Cape Town 1806, Montevideo 1807, Sarepta 1808, Valparaiso 1810, Astrakhan 1815, in Sumatra and at Hobart Town and Santiago (in Chili) in 1818, in Persia (at Teheran) in 1820, and at Chios about 1821.²

Customs of early printers.

Till the moment (say 1477) that printing spread to almost all the chief towns of Germany, Italy, Switzerland, France, the Netherlands, Spain, England, not a single printer carried away with him a set of types or a set of punches or moulds from the master who had taught him, but, in setting up his printing office, each man cast a set of types for his own use, always imitating as closely as possible the handwriting of some particular manuscript which he or his patron desired to publish. When we compare Schoeffer's 80-line indulgence of 1454 with a manuscript copy of the same indulgence dated 10th April 1454, now in the hands of a private collector at Wiesbaden, we see that the types used in printing that document were specially cast for the purpose after the model of the handwriting employed for the written copies. We know also that the types of the 36-line and 42-line Bibles and those of the psalter of 1457 are the closest possible imitations of the ornamental church handwriting customary at the time of their production. Also, when we compare the 31-line indulgence of 1454 with the German block-book called the *Enndtchrist*, and both in their turn with the German MSS. of that period (especially the manuscript portions in the printed copies of the indulgences), we see that the cutter of the text type of the indulgence, as well as the engraver of the block-book, formed his characters according to some German handwriting (book hand) of the period. This imitation extended, not only to the shape of the letters, but likewise to all those combinations of letters (double *p*, double *f*, double *s*, *st*, *ti*, *tu*, *re*, *cu*, *et*, *si*, *de*, *co*, *ci*, *te*, *ce*, *or*, *ve*, *po*, *fa*, *he*, *be*, &c.) and contractions (for *pro*, *-um*, *-em*, *-en*, *the*, *uer*, *-bus*, *-bis*, *sed*, *am*, *tur*, *qui*, *quæ*, *quod*, *secundum*, &c.) which were then, and had been for many centuries, in use by scribes. In most, if not all cases, the MSS. which the printers

imitated were indigenous to the place where they settled. Thus the first printers of Subiaco, though they were Germans and had most probably learned the art of casting types and printing at Mainz, clearly cut their types after the model of some Italian MS. which was free from any Gothic influence, but written in a pure Caroline minuscule hand, differing but slightly from the Caroline minuscules which the same printers adopted two years afterwards at Rome. The first Paris printers started in 1470 with a type cast in the most exact manner, on the model of the Caroline minuscule handwriting then in vogue at Paris. John de Westphalia, who introduced printing into Belgium, used from the beginning a type which he calls Venetian. Where therefore there is a great similarity, but no absolute identity, between the types of two printers (e.g., Schoeffer and Ulr. Zell), it should be attributed to the similarity of the handwritings which the printers followed rather than to any attempt on their part to imitate each other's types. To this universal system (clearly discernible in the first twenty-five years of printing) of each printer setting up business with a new type cast by himself, there are, according to the conjectures of a good many bibliographers, only two exceptions. One is Albrecht Pfister (see above); the other is the Bechtermunczes of Eltville (see above).

Another most important feature in the earliest books is that the Uneven-printers imitated, not only the handwriting, with all its contractions of tions, combined letters, &c., but all the other peculiarities of the lines. MSS. they copied. There is in the first place the unevenness of the lines, which very often serves as a guide to the approximate date of a book, especially when we deal with the works of the same printer, since each commenced with uneven lines, and gradually made them less uneven, and finally even. This unevenness was unavoidable in manuscripts as well as in block-books; but in the earliest printed books it is regarded as evidence of the inability of the printers to space out their lines. If this theory be correct, this inability was perhaps owing to the types being perforated and connected with each other by a thread, or to some other cause which has not yet been clearly ascertained. But it is not impossible that the unevenness was simply part and parcel of the system of imitating MSS., and that only gradually (about 1473 or 1474, but in some cases later) printers began to see that even lines looked better than uneven. This seems clear when we observe that the imitation of MSS. was carried so far that sometimes things which deviated from the work of the scribe, but had accidentally been printed in, were afterwards erased and altered in conformity with the MS. The Paris library, for instance, possesses two copies of the *Liber Epistolarum* of Gasparinus Pergamensis (printed at Paris in 1470) in both of which the initial *G* of the first line and the initial *M* of the fourth line were printed in, and, whilst they have been allowed to remain in one of the copies, in the other they were regarded as a fault and replaced by a rubricated *L* and *M*.

In the second place the initials of books or the chapters of books Initials, in MSS., and again in block-books and the earliest products of printing, were always, or at least in most cases (they are printed in the indulgences of 1454), omitted by the scribe and the printer, and afterwards filled in by the rubricator. As the latter artists were sometimes illiterate and very often filled up the gap by a wrong initial, we find in a good many MSS. as well as early printed books small letters written either in the margin or in the blank left for the initial, to guide the rubricator. In most cases where these letters (which are now called initial directors) were written in the margin, they were placed as much as possible on the edges of the pages in order that they might be cut away by the binder as unsightly; but in a vast number of incunabula they have remained till the present day.³ After a few years these initial directors were in a good many books printed in (in lower-case type) with the text. In all cases, whether written or printed, they were meant to be covered by the illuminated initial; but, as a matter of fact, the latter very seldom covers the initial director so completely as to make it invisible, and in a good many cases the intended illumination was never carried into effect.

With respect to the hyphens, which were used in the 1454 Hyphens, indulgences and the 36-line and 42-line Bibles, always outside the printed margin, some of the earliest printers did not employ them at the moment that they started their presses, and in the case of some printers the non-use or use of hyphens, and their position outside or inside the printed margin, serve as a guide to the dating of their products. After about 1472 they become more uniform in their shape and more generally used.

The use of signatures is confined in MSS. mostly to mark the Signatures, and in block-books to mark each sheet or page; they do not occur in printed books before 1472 (at least in no earlier book with a date), when they appear in Joh. Nider's *Præceptorium Divinæ Legis*, published by Johan Koelhoff at Cologne.

Catchwords (*custodes*) were used for the first time about 1469 by Catch-words, Johannes of Spire, at Venice, in the first edition of Tacitus.

¹ See Rob. Dickson, *Introd. of Art of Print. into Scotl.*, Aberdeen, 1885.

² On the introduction of printing in various towns, consult Henry Cotton, *A Typog. Gazet.*, 8vo, Oxford, 1881 and (second series, 8vo, Oxford) 1886; (F. Deschamps) *Dict. de Géogr. et d'Usage du Libraire*, 8vo, Paris, 1870; R. C. Hawkins, *Titles of the First Books from the Earliest Presses Established in Different Cities in Europe*, 4to, New York, 1884.

³ The university library of Basel possesses a collection of the earliest Paris books still bound in their original binding, in which these initial directors are written not only on the outer edges but on the inner sides of the pages, and so close to the back that they can only be seen by stretching the books wide open.

Pagina-
tion.

Pagination or rather foliation was first used by Arn. Ther Hoernen, at Cologne in 1471, in Adrianus's *Liber de Remediis Fortuitorum Casuum*, having each leaf (not page) numbered by figures placed in the end of the line on the middle of each right-hand page.

Slowness
of pro-
gress at
first.

The practice among early printers of imitating and reproducing MSS. was not abandoned till many years after the first printed book (1454) made its appearance; and, looking at the books printed, say from 1454 to 1477, from our present standpoint of daily improvement and alteration, the printing of that period may be said to have been almost wholly stagnant, without any improvement or modification. If some printers (for instance, Sweynheym and Pannarts at Subiaco and Rome, and Nicolas Jenson at Venice) produced handsomer books than others, this is to be attributed to the beauty of the MSS. imitated and the paper used rather than to any superior skill. Generally speaking, therefore, we shall not be very far wrong in saying that the workmanship of Ketelaer and De Leempt's first book, published at Utrecht c. 1473, and that of Caxton's first book issued at Westminster in 1477, exhibit the very same stage of the art of printing as the 1454 indulgences. If therefore any evidence were found that Ketelaer and De Leempt and Caxton had really printed their first books in 1454, there would be nothing in the workmanship of these books to prevent us from placing them in that year. And conversely, if the indulgences of 1454 had been issued without a date or without any names to indicate their approximate date, their workmanship would invariably induce bibliographers to ascribe them to circa 1470, if not somewhat later. Even after 1477 the alterations in the mode of printing books proceeded very slowly and almost imperceptibly. It came to be no longer a universal system for printers to begin business by casting a type for themselves, but some received their types from one of their colleagues. And, though there were still many varieties of types, one sort began to make its appearance in two or three different places. The combinations of letters were the first to disappear; but the contractions remain in a good many books even of the 17th century.

Some theories have been based on, and others have been considered to be upset by, the supposition that the early printers always required as much type as printers of the present day, or at any rate so much as would enable them to set up, not only a whole quire of 4 or 5 sheets (= 8 or 10 leaves = 16 or 20 pages), but even two quires (= 40 pages). Consequently calculations have been made that, for instance, the printer of the 42-line Bible required a fount of at least 120,000 characters.¹ But, though the *Speculum Humanæ Salvationis* seems to have been printed by whole sheets (2 pages), there are numberless proofs that many early books were printed page by page, even when in small 4to. For instance, in some books it has been observed that portions of the types with which the text of the first, second, or third pages of a quire had been printed were used to "lock up" the types employed for the later pages of the same quire, as is evident from the blank impressions of such portions being found on these later pages. Again, in some books two, three, or four blank leaves are found at the end, showing a miscalculation of the printer. Moreover, the numerous itinerant printers of the 15th century, who established a press for a short time wherever they went, prove that the furniture of the earliest printing offices must have been of no great extent.

The Invention Controversy.

Contro-
versy as
to inven-
tion of
printing.

Now that we have traced the art of printing from the moment (1454) that it made its appearance in a perfect state at Mainz, and have followed its spread to all the chief places of Europe till 1500, we must take notice of the controversy which has been carried on for nearly four hundred years as to when, where, and by whom the art was invented. For this purpose we will gather up into a chronological sequence (a) a few of the most important expressions used by the earliest printers in their colophons, (b) whatever documentary evidence there may be on the subject, and (c) some accounts of the earliest authors on the subject. (The letters A, B, &c., are for the sake of convenient reference.)

Early
testi-
monies;

The earliest testimony (A) to which we may refer is the notarial instrument, dated 6th November 1455, of the lawsuit between Fust and Gutenberg, whereby the former sought to recover 2026 guilders from the latter in repayment of 1600 guilders (800 advanced in 1450 or 1449 and another 800 in 1452), with the interest thereon. Fust speaks here² of "the work" (line 24), and of "our common work" (line 60); Gutenberg speaks of "tools" in preparation, "workmen's wages, house-rent, vellum, paper, ink, &c." (lines 37-40), of "such work" (41), and of "the work of the books" (42);

¹ See Bernard, *Origine de l'Impr.*, i. 164, who was a printer himself and speaks very strongly on this point.

² We quote from the text of the instrument as published by J. D. Koehler, *Ehren-Rettung Johann Gutenberg's*, Leipzig, 1741.

whereas the judges speak of "the work to the profit of both" (49), and "their common use" (60). (B) In the earliest³ book published with a date (the Mainz psalter, issued 14th August 1457 by book Fust and Peter Schoeffer) it is said that it was perfected at Mainz colophony by an "adinventio artificiosa imprimendi ac caracterizandi absque colonis, calami ulla exaratione" (repeated and varied later; see p. 681 above). &c.; (C) In 1460 the *Catholicon* was published at Mainz, without the name of the printer; but the colophon, after stating that the book was printed at Mainz, which town God's mercy had deigned to prefer above other nations of the earth, adds (D) that the book was printed and completed "non calami, stilli, aut pennæ suffragio, sed mira patronarum formarumque concordia, proporcione, et modulo." This work is considered to have been printed by Gutenberg, and the mention of God's mercy is regarded as an allusion to the invention of printing. The phrase is, however, also found in the *Liber Sextus Decretalium*, in the *Summa* of Thomas Aquinas, and in the *Clementinæ*, published respectively on 17th December 1465, 6th March, and 8th October 1467, by Fust and Schoeffer. (E) On 17th January 1465 Adolph II., archbishop of Mainz, by a public decree, appointed Gutenberg as his servant in reward for "his services," but he does not speak of him as the inventor of printing, nor even as a printer. (F) In the *Grammatica Rhythmica*, published in 1466 by Fust and Schoeffer, the third line of the colophon runs: "Hinc Nazareni sonet oda per ora Johannis," which was formerly regarded as an allusion to Johann Fust or Johann Gutenberg, but which more probably refers to Johann Brunnen or Fons, the author of the grammar. (G) On 26th February 1468 Dr Homery wrote to the archbishop of Mainz the letter quoted above, from which it may be inferred that Gutenberg had been a printer, though not a word is said as to his being the inventor of printing. (H) In 1468 Schoeffer reprinted Fons's *Grammatica*, and in the colophon it is said: "At Moguntina sum fusus in urbe libellus meque (the book) domus genuit unde caragma venit." (I) Schoeffer published on 24th May 1468 the first edition of *Justiniani Imper. Institutionum Juris Libri VI., cum Glossa*. To this were added by way of colophon some verses commencing: "Secunda tabernaculi, &c.," in which it is said that (the ornament of the church) Jesus "hos dedit eximios sculpendi in arte magistros. . . Quos genuit ambos urbs Moguntina Johannes, librorum insignes prothocaragmaticos," which is regarded as an allusion to Johann Gutenberg and Johann Fust as first printers. (K) In the same year (1468) Johannes Andreas, bishop of Aleria, says, in the dedication of his edition of St Jerome's *Epistles*, published in that year (18th December) at Rome, to Pope Paul II., that "Germany is to be honoured for ever as having been the inventress of the greatest utilities. Cardinal Cusa wished that the sacred art of printing, which then (under Cardinal Cusa, who died 11th August 1464) seemed to have arisen in Germany, were brought to Rome." (L) In 1470 Guil. Fichet, in an octastichon inserted in the Paris edition of 1470 of the *Letters* of Gasparinus of Bergamo, exhorts Paris to take up the almost divine art of writing (printing) which Germany is acquainted with. In the same year Erhard Windsberg writes to the same effect in an epigram inserted in the *Epistolæ Phalaridis* published at Paris about 1470. (M) In 1471 Ludov. Carbo speaks, in the dedication of the *Letters* of Pliny to Borso, duke of Modena, of the Germans having invented printing. Nicolaus Gupalatinus speaks (Venice, 1471) of a German being the inventor of printing, and Nicolaus Perottus of the art which had lately come from Germany. (N) On 21st May 1471 Nicolas Jenson published an edition of Quintilian, edited and revised by Ognibene de Lonigo (Omnibonus Leonicensis), who in the preface speaks of its printer as "librarie artis mirabilis inventor, non ut scribantur calamo libri, sed veluti gemma imprimantur, ac prope sigillo, primus omnium ingeniose demonstravit." (O) About 1472 the first three printers of Paris published Gasparinus Pergamensis's *Orthographia Liber*, to which is prefixed (in the copy of the university of Basel) a letter, dated 1st January, from Guillaume Fichet, prior of the Sorbonne, to Robert Gaguin, in which he says that "it is rumoured in Germany that not far from the city of Mainz a certain Johann Gutenberg (Johannes, cui cognomen Bonemontano) first of all invented the art of printing (impressoriam artem), by means of which books are made with letters of metal, not with a reed (as the ancients did), nor with the pen (as is done at present)." (P) On 14th July 1474 Joh. Philippus de Lignamine published at Rome *Chronica Summorum Pontificum Imperatorumque*, in which we find, between two entries, relating one to 14th July 1459 and the other to 1st October 1459, an undated paragraph in which it is said that Jacobus with the surname of Gutenberg of Strasburg and a certain other one named Fustus, "imprimendarum litterarum in membranis cum metallicis formis periti, trecentas cartas quisque eorum per diem facere innotescunt apud Moguntiam Germanie civitatem." The same is said of Mentelin, and (under 1464) of Conrad Sweynheym, Arnold Pannarts, and Udalricus Gallus. (Q) On 23d May 1476 Peter Schoeffer issued the third edition of the *Institutiones* of Justinian, with the same imprint as in the edition

³ The earliest is perhaps the *Donatus* issued by Peter Schoeffer, possibly before 1466, the colophon of which says that it was finished: "Arte nova imprimendi seu caracterizandi . . . absque calami exaratione."

From
docu-
mentary
evidence.

of 1468 (see testimony I), but with the addition that Mainz is the "impressoriaris artis inventrix elimatrixque prima." (R) In 1478 an edition of the *Fasciculus Temporum* was issued at Cologne, in which it is stated under the year 1457 that the printers of books were multiplied on earth, deriving the origin of their art from Mainz. The earlier editions merely stated that the printers of books were multiplied on earth. (S) In 1483 Matthias Palmerius of Pisa published at Venice the *Chron. Euseb.*, in which under the year 1457 it is stated that students owe a great debt to Germany, where Johannes Gutenberg zum Jungen, knight of Mainz, invented the art of printing in 1440. (T) In the same year Jac. Phil. Foresta of Bergamo published *Supplementum Chronicorum*, in which he says under the year 1458 that the art of printing books was first discovered in Germany, according to some by Guthimberg of Strasburg, according to others by Faust (see P), according to others by Nicolas Jenson (see N). (V) On 6th March 1492 Peter Schoeffer published the *Niedersächsische Chronik* of Conrad Botho, saying in the colophon that it was "geprent . . . in . . . Mentz, die eyne anefangk is der prentery." (X) At the end of 1494 two Heidelberg professors, Adam Wernher and Joh. Herbst, composed some Latin verses in honour of Johannes Gensfleisch (a family name by which Gutenberg was known, and which was turned into the Latin Ansicarus), whom they called "primus librorum impressor" and "impressoriaris artis inventor primus."¹ (Y) In 1499 Jacobus Wimpheling (born at Schlettstadt 1450, died 1528) published (at Mainz, by P. Friedberg) an *Oratio in Memoriam Marsilii ab Inghen* (d. 1396), in which he, on leaf 22a, praises Joannes Ansicarus in verse on account of his invention at Mainz. (Z) These verses are preceded by an epitaph on Johann Gensfleisch, "artis impressoriaris inventor" and "reperor," written in Latin by Adam Gelthus, a relative of Gutenberg. (AA) In the same year Polydore Vergil (*De Inventoribus Rerum*, Venice, 1499, lib. ii. cap. 7) says that a certain Peter [Schoeffer?], a German, invented in 1442 the art of printing at Mainz in Germany, as he had heard from the latter's countryman; this statement was repeated in a Venice edition of 1503. In later editions "Peter" was altered to "Joh. Gutenberg." (BB) In the same year Koelhoff, printer at Cologne, published *Cronica van der hilliger Stat van Coellen*, in which on fol. 312b it is said: (1) The art of printing was found first of all in Germany at Mainz about the year 1440; (2) from that time till 1450 the art and what belonged to it were investigated; (3) and in 1450, when it was a golden year (jubilee), they began to print, and the first book that they printed was the Bible in Latin, in a large letter, resembling that with which at present missals are printed. (4) Although the art was found at Mainz in the manner in which it is generally employed now, yet the first prefiguration was found in Holland from out the *Donatuses* which were printed there before that time, and from and out of them was taken the beginning of the aforesaid art, and it was found much more masterly and exact (*subtiliter*) than that other manner was, and has become more and more artistic. (5) Omnibonus wrote in a preface to Quintilian, and in some other books too, that a Walloon from France, named Nicol. Jenson (see N), discovered this art; but that is untrue, for there are those still alive who testify that books were printed at Venice before Nicol. Jenson came there, and began to cut and make letters. (6) But the first inventor of printing was a citizen of Mainz, named Junker Johan Gudenburch. (7) From Mainz the art was introduced first of all into Cologne, then into Strasburg, and afterwards into Venice. (8) The origin and progress of the art were told to the writer verbally by Ulrich Zell of Hanau, still printer at Cologne (anno 1499), through whom the said art came to Cologne. (CC) In 1501 Jacob Wimpheling (see Y), who stated in his *Oratio Querulosa contra Invasores Sacerdotum, Flammarum*, &c., published at Delft c. 1495, that chalcography had been invented at Mainz, published a work (*Germania*, Strasburg, Joh. Prüss, 1501) in which he says (on p. 43) that the invention was made at Strasburg by Johann Gutenberg of Strasburg, and that it was perfected at Mainz. (DD) In 1503 Johann Schoeffer (the son of Peter Schoeffer and the grandson of Johann Fust) published an edition of *Hermes Trismegistus*, in which he represents himself as one of the most distinguished citizens of Mainz, descended from the most fortunate race who invented the art of printing. (EE) In 1504 Ivo Wittig, who was a relative of Gutenberg, and a canon and the keeper of the seal of the St Victor cathedral near Mainz (of which Gutenberg had been a lay member), erected in the house "Zum Gutenberg" a memorial stone and an epitaph to Joh. Gutenberg of Mainz, "qui primus omnium litteras ære imprimendas invenit." (FF) In 1505, in the German translation of Livy published by Johann Schoeffer (see KK), the dedication to the emperor Maximilian, which was probably written by Ivo Wittig (see EE), speaks of Johann Güttenbergk as inventor of printing (1450) and Johann Faust and Peter Schoeffer as improvers of the art. This work was reprinted six times (1514, 1523, 1533, 1551, 1553) with the same dedication; but in 1509 the *Breviarium Moguntinum* says that it was printed at the expense and trouble of Johann

Schoeffer, whose grandfather (i.e., Johann Fust) was the first inventor and author of the art of printing (see DD). (GG) In 1505 Jacob Wimpheling, in his *Epithoma Germanorum* (Strasburg, 1505), asserts (on leaf xxxviii b. and xxxix a.) that in 1440 Johann Gutenberg of Strasburg invented there the art of printing. And in 1507, in his *Catal. Episcoporum Argent.* (Strasburg, 1507), he says that the art was invented, though in an imperfect manner, by a certain Strasburger, who afterwards went to Mainz and joined others working and trying the same art, where it was, under the guidance of Johann Gensfleisch, perfected in the house "boni montis" (Gutenberg). This he repeated in 1515. (HH) About 1506 Johannes Trithemius wrote his *Chronicon* of Spanheim, published at Frankfurt in 1601, in which he says (p. 386) that the art of printing books was discovered afresh at Mainz by Johan Gutenberg, who, after having spent all his property in accomplishing the new invention, perfected it by the advice and assistance of Johann Fust. The first propagator of the new art was, after the inventor, Peter Schoeffer. (II) In 1515 Johann Schoeffer published Joh. Trithemius's *Compendium sive Breviarium Historiæ Francorum*, and said in the colophon that the book was published at Mainz, the first inventress of the art of printing, by Johann Schoeffer, grandson of the late Johann Fust, the first author of the said art, who finally from his own genius commenced to excogitate and to investigate the art in 1450, and in 1452 perfected it and commenced printing, assisted by many necessary inventions of Peter Schoeffer von Gernsheim, his servant and adopted son. Johann Fust and Peter Schoeffer kept this art secret, binding all their servants and domestics by oath never to reveal it; but in 1462 it was spread by the same domestics into divers countries. (KK) On 9th December 1518 the emperor Maximilian accorded to Johann Schoeffer the privilege of printing Livy (1518-1519), and says in it that "he has learned and been advised on the faith of worthy testimonies that the ingenious invention of chalcography was effected by the printer's grandfather." (LL) In 1519 Joh. Thurmayer Aventinus (1474-1534) wrote that "in 1450 Joannes Faustus, a German, a citizen of Mainz, invented a new kind of writing, called chalcography, and completed it in two years; it was kept secret by him and Peter Schoeffer, his son-in-law, but divulged in Germany ten years afterwards by Faust's servant, Johannes Güttenberger, a Strasburger." (MM) In a pedigree of Lourens Janszoon Coster of Haarlem and his descendants, drawn up not later than 1520, it is asserted that in 1446 "he brought the first print into the world." This document, of which the date 1446 seems to have been altered into 1440, is preserved in the Haarlem town library. (NN) In 1520 Johan Schott, a printer at Strasburg and grandson of Johan Mentelin, the first printer of that town, published an edition of Ptolemy, at the end of which he printed the arms of his grandfather with the following legend: "Insigne Schottorum Familiae ab Friderico Rom. Imp. III. Joan. Mentelio primo Typographiae Inventori ac suis concessum: Anno Christi 1466." Apart from the assertion that Mentelin was the inventor of printing, we may remark that the emperor Frederick III. raised Mentelin to the rank of a nobleman in 1466 and granted him new arms. (OO) About 1533 the Neapolitan Mariangelo Accorso, who had resided at the court of Charles V., wrote on an edition of *Donatus* (in the possession of Aldus Manutius, jun.) that "Joh. Faust of Mainz first discovered the art of printing with metal types, which afterwards he made of lead; his son Peter Schoeffer added afterwards much to polish the said art. This *Donatus* and *Confessionalia* were printed first of all in 1450. Faust derived the suggestion from a *Donatus* printed before in Holland from an engraved block." This paragraph is found on p. 411 of the *Biblioth. Apost. Vaticana* of Angelo Rocca (Rome, 1591). Some consider its latter part to have been derived from the *Cologne Chronicle* (BB), and it seems probable that it was a mixture of some of the above testimonies. (PP) In 1536 Johan Schott (see NN) published *Historien Handt-Buchlein* (Strasburg, 1536), in which (on leaf b¹ and b²) he says that "Hans Mentlin of Strasburg invented the art, which, through infidelity, was brought to Mainz." On the strength of this and other statements (CC, GG, NN) the bicentenary of the Strasburg invention was celebrated there in 1640. (QQ) In 1541 Joh. Arnold (Bergel or) Bergellanus, who had settled as press-reader at Mainz two years previously, published his *Encomium Chalcographiæ* (Mainz, Fr. Behem, 1541, 4to), in which the lawsuit between Fust and Gutenberg (A) is alluded to for the first time. Bergel had read Trithemius's books (HH), in which the invention is ascribed to Johann Gutenberg with two coadjutors, Johann Faust and Peter Schoeffer, which he (Bergel) had heard confirmed in conversations with Mainz citizens; he had also seen some old tools prepared for the work by the originators which were still in existence. Gutenberg invented it in 1450. (RR) About 1561 Jan Van Zuren (born at Haarlem in 1517) and Dirk Volkerts Coornhert (born at Amsterdam in 1522) established a printing office at Haarlem. Of the former it is alleged that he had compiled a work on the invention of printing, which is presumed to have been lost during the siege of Haarlem in 1573. It was not publicly spoken of till 1628, when Peter Scriverius published his *Laurecrantz voor Laurens Coster*. Scriverius had only found the

¹ These verses were not published at the time, but in the 19th century by F. J. Mone, *Quellenamml. der bad. Landesgesch.*, iii. 168, from the contemporary MS. of Adam Wernher, preserved in the archives of Karlsruhe.

title, preface, and introduction, in which Van Zuren contended that the first foundations of the art were laid at Haarlem, and that it afterwards accompanied a foreigner to Mainz. In this introduction he does not mention the name of the inventor, nor a date, but points in indefinite terms to the house of the inventor as still existing. (SS) In the same year (1561) Van Zuren and Coornhert published an edition of the *Officia Ciceronis*, in which the latter, in a dedication to the magistracy of Haarlem, refers to the rumour that the art of printing books was invented first of all at Haarlem, and was brought to Mainz by an unfaithful servant and much improved there. He adds that very old and dignified persons had often told him, not only the family of the inventor, but also his name and surname, and had explained the first crude way of printing, and pointed out to him the house of the first printer. (TT) In 1566 Luigi Guicciardini, a Florentine nobleman who had visited the Netherlands and had resided many years at Antwerp, finished a description of the Netherlands (published in 1567), in which, alluding to Haarlem, he speaks of the invention there according to the assertions of the inhabitants, the evidence of some authors, and other remembrances; the inventor died before the perfection of his art; his servant went to Mainz, where he perfected the art, and hence the report that it was invented there. (VV) About 1568 (it is calculated) Hadrianus Junius wrote his *Batavia*, published at Leyden in 1588, with two prefaces, dated, the one from Leyden, 6th January 1575, the other from Delft *ad annum salutis* 1575. On p. 253 he says that the opinion that the forms of the letters whereby books are printed were first discovered at Mainz is very inveterate, but old and eminent inhabitants of Haarlem had assured him that they had heard from their ancestors that there lived at Haarlem, more than 128 years before, in a decent house then existing, near the market-place, opposite the royal palace, Lourens (son of) Jan, surnamed Coster, who, while walking in the wood near Haarlem, began to shape beechen bark first into figures of letters, by which, reversely impressed one by one on paper, he composed one or two lines to serve as an example for the children of his son-in-law. When this succeeded, he began to contemplate greater things, and first of all invented, assisted by his son-in-law Thomas (son of) Peter, a more gluey and substantial kind of ink (as the ordinary ink was found to blot), with which he printed whole tablets with pictures, with the letters added. Junius had seen books of this kind printed by Coster (the beginnings of his labours) on the rectos of the leaves only, not on both sides; the book was written (in Dutch) by an anonymous author, and entitled *Speculum Nostræ Salutis*, in which care was taken that the blank versos could be pasted together, so that the blank pages should not present any unsightliness. Afterwards (Coster) changed the beechen characters into leaden, and the latter again into tin ones. Very ancient wine-pots cast of the remains of these types were still to be seen in the house of Lourens, which was afterwards inhabited by his great-grandson Gerard (son of) Thomas, who had died an old man a few years before. When the new merchandise attracted purchasers everywhere, workmen were added to (Lourens's) household, among whom was a certain John (whether, as was suspected, Faust, or another of the same name, Junius did not inquire), who was bound to the work of printing by oath. But, when he thought he knew the art of joining the letters and of casting the types, &c., he stole away, when everybody had gone to church, the whole apparatus of the types and the tools prepared by his master, and hastened to Amsterdam, thence to Cologne, until he arrived at Mainz, where he could remain in safety, and, having opened a work-office, issued within the space of one year, about 1442, the *Doctrinale* of Alexander Gallus and the *Tracts* of Petrus Hispanus, printed with the same types which Lourens had used at Haarlem. Junius recollects that Nicolaus Gale, his tutor, a man of firm memory and venerable old age, had told him that as a boy he had often heard a certain bookbinder Cornelis (a man of more than eighty years of age, who had been an under-workman in the same office) narrating the story of the invention (as he had heard it from his master), the polishing and increase of the crude art, &c., and cursing those nights which he had passed, during some months, with the culprit in one bed. The burgomaster Quirinus Talesius admitted to Junius that he had formerly heard nearly the same from the mouth of the same bookbinder. (XX) In 1628 Scriverius in his *Laurecrantz* (see RR) placed the date of the Haarlem invention as far back as 1428, and mentioned as its inventor Lourens Janszoon, sheriff of Haarlem. He asserts that the art of printing appeared, "not in the manner as it is used now, with letters cast of lead and tin, but a book was cut leaf for leaf on wooden blocks," and the Haarlem inventor was robbed in 1440 by Johan Gutenberg. Scriverius based the date 1428 upon a Hebrew *Chronicle* compiled by Joseph ben Meir (born 1496, d. c. 1575), and published in 1554 at Sabionetta by Cornelius Adelkind, where, under the year of the Jewish era 5188 (=1428), the author mentions a book (without giving the title) printed at Venice and seen by him. Scriverius, being convinced that this could only refer to a book printed at Haarlem, applied the entry to a xylographic *Biblia Pauperum*, of which he gave a description, together with several other block-books and early printed books.

(YY) In 1639 Boxhorn pushed the date of the Haarlem invention back to 1420, referring, as his authority, to the same *Chronicle* of Rabbi Joseph. Since that time the date of the Haarlem invention has been variously placed between 1420 and 1430.

Later testimonies are mere repetitions of earlier state-claims.¹ We need not say much about the story of Antonio Cambruzzi, who asserted that Pamfilo Castaldi invented printing at Feltre, in Italy, in 1456, and that Fausto Comesburgo, who lived in his house in order to learn the Italian language, learned the art from him and brought it to Mainz; this story, however, has found so much credence that in 1868 a statue was erected at Feltre in honour of Castaldi. Nor need we speak of Kuttentberg in Bohemia, where John Gutenberg is asserted to have been born and to have found the art of printing. We may also pass over Johann Fust, later on called Faust (testimonies P, T, DD, FF, II, KK, LL, OO), as we know from the Mainz lawsuit of 1455 (A) that he had simply assisted Gutenberg with loans of money. We may also pass over Johann Mentelin of Strasburg (testimonies NN, PP), only remarking here that he had already printed a Bible in 1460, and that he is mentioned in Strasburg registers as a chrysographer or gold-writer from 1447 to 1450; but of his whereabouts between 1450 and 1460 there is no record. That he had gone, or had been called, after 1450 by Gutenberg to Mainz has been asserted but not proved, and there is no reason why he should not be one of the two Johannes alluded to as the *prothocaragmatici* of Mainz in the Justinian of 1468 (testimony I.). That Nicolas Jenson came to be regarded in certain circles and for a time as the inventor of printing is owing to testimony N being misunderstood. There remain, therefore, to be considered the testimonies which bear on the rival claims of Haarlem and Mainz. The controversy between Germany and Holland was publicly started as early as 1499 by the *Cologne Chronicle* (testimony BB), that between the two towns mentioned not publicly before 1561 (testimony RR); while no rival inventor to Gutenberg was mentioned publicly and in print earlier than 1588 (testimony VV).

Let us first consider the claims of Germany and Mainz as centred in the person of Henne (=Hans or Johann) Gensfleisch, called Gutenberg or Gudenberg, the latter name derived from his mother, berg, whose maiden name was Elsa Wyrich, who lived in the "Hof zum Gutenberg" at Mainz. He is supposed to have been born at that town about 1400. He is first mentioned in a Mainz document, dated 16th January 1430. In a document of 28th March 1430 he is spoken of as being "not in Mainz." Documents from 14th March 1434 to 18th September 1444 prove him to have been at Strasburg during that time, and documents dated respectively 17th October 1448, 6th November 1455, 21st June 1457, 10th April 1461, show that he was in or near Mainz on those days. By a decree of 17th January 1465 the archbishop of that town rewarded him for "his services," and in the bond of Dr Homery, dated 26th February 1468, he is spoken of as dead. There are, moreover, six forged documents (including some relics of an ancient press bearing the date 1441) respectively dated 24th March 1424, 1437, 3d July 1453, 20th July 1459, 19th June 1463, and an entry in an annuarius which has been applied to Gutenberg, but does not concern him (see Hessels, *Gutenberg*).

In former years, when printing was believed to have been invented in 1440, the records of the Strasburg lawsuit of 1439, between Gutenberg and some Strasburg artisans about certain industrial undertakings (as the art of polishing stones, the manufacture of looking-glasses), were considered to prove the invention of printing at Strasburg, not, however, by Mentelin, as had been thought by some (testimonies NN, PP), but by Gutenberg. The records came to light about 1740, just when Schoepflin, the principal discoverer, had been commissioned to search for documents of this kind. Doubts may be suggested as to their genuineness, but they have all perished, partly during the revolution of 1793 and partly during the siege of Strasburg in 1870. However, nobody would now assert that printing was invented in 1439 or at Strasburg; and those who still believe that Gutenberg was the inventor of printing refer to them only as showing that he was a mechanic as early as 1439, and that he understood the art of pressing.²

¹ Over a hundred of them have been collected by Ger. Meerman, *Origines Typogr.*, ii. p. 58 sq.

² See Hessels, *Gutenberg*, pp. 23, 135, &c.

The first document that connects Gutenberg with the art of printing is the notarial instrument of 6th November 1455 (testimony A). But it says nothing of an invention or a new mode of printing. And yet the occasion was such as to make it almost imperative on Gutenberg to mention it, for he had spent 1600 guilders of Fust's money, apparently without printing anything,¹ and was on the point of being robbed by the latter and having taken away from him all that he had made and done to give effect to his idea or invention. In the next testimony (B), *i.e.*, the earliest Mainz books with printed dates (1457 to 1467), there is evidence that the new art of printing is not only not kept secret but fully appreciated at Mainz, and its importance fully realized and advertised; but, though they speak of a "nova ars imprimendi" and an "adinventio imprimendi," there is not a syllable as to a Mainz invention or inventor. In testimonies C and D (the *Catholicon* of 1460) there is again not one word about an invention or an inventor, or about Mainz. Yet Gutenberg is supposed to have printed the *Catholicon*; and it is incredible that he, who had been wronged and robbed by his two rivals (Fust and Schoeffer), should agree with them in explaining and proclaiming the new art, but never with one word assert his claim to the honour and profit of the invention, if he had made any, and should even omit his name, whereas he saw his two rivals never neglect to print their names in full on every book which they published. Those who believe that Gutenberg was the inventor of printing suggest that he kept silent, as otherwise his creditors would have seized his copies and his printing office. But this explanation cannot be accepted; for the verbose colophon at the end of a gigantic folio book like the *Catholicon*, published at a time when there were perhaps not more than three printing offices in the world, was calculated to draw attention to its printer and his residence, not to conceal him. Testimony F (1466) is no longer regarded as having any reference to Gutenberg or the invention of printing. H (1468) was formerly thought to mean: "I, the book, am cast (*i.e.*, its types are cast) in the Mainz city, and the house whence the type came (=where the type was invented) produced me." But of late years it has been shown that the author of the book, Johann Fons, was Peter Schoeffer's press-corrector. And, as he no doubt resided in Schoeffer's house, the two lines evidently mean: "I am a little book cast in Mainz, and I was born (=written) in the same house whence the type comes" (=where I am printed)." Testimony I (also of 1468) speaks of two Johannes (Gutenberg and Fust) as the "prothocragmatici librorum quos genuit urbs Moguntina." But this certainly means, not that the first printers of books were born at Mainz, but that the two Johannes were the chief printers of books (born) produced at Mainz.

When we now place together the clear documentary testimonies (A to I) of the first fourteen years of printing (1454 to 1468) at Mainz, we see that they all come from Mainz itself. Everybody connected with the art speaks of it in the most public and unreserved manner; its importance is as fully realized and advertised during that period as it is in the present day; the German nation is even congratulated on possessing it; there is never any secrecy about it; once (about 1456) it is even called a new art. But, in the midst of all this publicity, the art which Mainz and Germany possess is never said to have been invented at Mainz. The supposed Mainz inventor (Gutenberg) even speaks himself on two occasions (in the lawsuit of 1455 and in the *Catholicon* of 1460), but never says that he had made an invention. The archbishop, too, speaks publicly of Gutenberg in 1465 (testimony E), and rewards him for services, but does not speak of him as the inventor of printing, nor even as a printer. Nor does Dr Homery, in his letter to the archbishop (testimony G), in which he refers to Gutenberg's printing apparatus, call him the inventor of printing.

In 1468 we enter on a new phase in the history of the invention. Even if we reject testimony I as being merely local, testimony K (1468) speaks of the art of printing as having arisen in Germany. This testimony, however, does not come from Germany, nor from Mainz, but from Italy, and is supposed to owe its inspiration to the two German printers who had established a printing office at Subiaco in 1465, and in 1467 at Rome, and who most likely learned their craft at Mainz. But, as the two printers are mentioned in the testimony, and as it does not speak of Gutenberg, nor of Mainz, it is far more likely that it was merely derived from the colophons of Fust and Schoeffer, or from something that Cardinal Cusa had heard during his embassies in Germany. To the Mainz colophons we must also ascribe (a) the two testimonies of 1470 (L) and (b) the three of 1471 (M), all five of which come from France and Italy. At last, in 1472, we find in testimony O the invention of printing ascribed to Gutenberg of Mainz, but it is mentioned as a rumour, and comes from France. Guil. Fichet of Paris, who gives it, is supposed to have heard the rumour from the three German printers

who commenced printing at Paris in 1470. But, as two of them had resided, immediately before they came to Paris, in the university of Basel, and are supposed to have learned their art there, the rumour is ascribed to "Bertolff von Hanauwe," who appears in the lawsuit of 1455 as Gutenberg's servant, and who was printing at Basel in 1468. Perhaps it came rather from information which Fichet obtained from the St Victor cathedral, near Mainz, as he speaks of the art having been invented not far from that town. Testimony P (1474) again comes from Italy, from Rome, and was perhaps derived from one of the German printers settled there at that time. It merely speaks of Gutenberg, Fust, and Mentelin as printers, but says not a word which even touches upon the invention of the art. In testimony Q (1476) we have definite mention of Mainz as the inventress of the art; it is given as an addition to the Mainz colophon of 1468 (see I). In 1478 Mainz is again mentioned in a Cologne testimony (R), which gives evidence of research, as it is an amplification of an earlier one in which Mainz was not mentioned. Germany, Gutenberg, and Mainz are again mentioned in the Venetian testimony S (1483), which gives for the first time 1440 as the date of the invention. In the same year we have two earlier testimonies (P and N) worked into one (T), to the effect that printing was invented either by Gutenberg or by Fust or by Jenson. Testimony V (1492), which states that printing commenced at Mainz, is practically equivalent to Q. In 1494 and 1499 we have three German testimonies (X, Y, Z) as to Gutenberg being the inventor of printing; these, however, come, not from Mainz, but from Heidelberg. Z is given by a relative of Gutenberg, Adam Gelthus; and, as the latter resided at Heidelberg, it is clear that he was the real source of the other two Heidelberg testimonies (X and Y). Two years later, when Wimpeling, the author of testimony Y, had left Heidelberg, he ascribed (OO) the invention of printing to Strasburg, though stating that Gutenberg was the inventor. Testimony AA is recorded above to show the great confusion that reigned in people's minds about the invention. We must add to these testimonies those of 1504 (EE) and 1505 (FF), which are owing to Ivo Wittig, a relative of Gutenberg, and a canon and the keeper of the seals of the St Victor cathedral, near Mainz, of which Gutenberg had been a lay member according to its *liber fraternitatis*. Thus in the period from 1468 to 1505 we have (1) several vague statements made in Italy and France as to the art of printing being known or practised or invented in Germany, statements which arose from the books and colophons published at Mainz; (2) one item of rumour in 1472 that Gutenberg invented it near that town; (3) two Mainz statements, of 1476 and 1492, and one Cologne statement, of 1478, that it was invented at Mainz; (4) three German statements, of 1492, 1494, and 1499, that Gutenberg had invented it; and (5) two Mainz statements, of 1504 and 1505, to the same effect. It is to be particularly noticed that the statements (2, 4, 5) which speak distinctly of Gutenberg being the inventor can be clearly traced to Gutenberg himself and two of his relatives.

Seeing then how slender the basis is for the tradition that Contraprinting was invented by Gutenberg at Mainz, and that even this diction of slender basis was not laid till fourteen years after the art had Gutenberg been fully established and proclaimed in that city, we cannot be surprised to find the tradition promptly contradicted. This contradiction was made in 1499 (testimony BB) in a *Chronicle* published at Cologne. To facilitate the understanding of this testimony it is divided above into eight sections. The first (taken from Hartmann Schedel's *Chronicle*, 1493), second, sixth, seventh, and eighth are no doubt due to the compiler of the *Chronicle*, and must not be connected with the third, fourth, and fifth, which, according to the compiler, are due to Ulrich Zell, a printer at Cologne, who had probably settled there about 1463, and had most likely learned his art at Mainz, as he called himself "clericus Moguntinus." As Zell's testimony leaves to Gutenberg nothing but the honour of having perfected the art, various attempts have been made to explain away this account. As long as no typographically printed *Donatus* had been found that could be fitted into Zell's account, it was argued that he meant *Donatuses* printed from wooden blocks; and this argument is brought forward even at the present time. But a practical printer like Zell must have been able to express himself to that effect if he had really meant to say so; and, as block-printing was not less practised in Germany than in Holland, we could hardly assume that things printed in Holland would have inspired the German inventor rather than the same things printed in Germany. That testimony OO speaks of a *Donatus* printed from wooden blocks may be ascribed to the notion arising at that time (c. 1533) that block-printing had given rise to typography. It has also been asserted that Holland in the *Chronicle* means Flanders; but the *Chronicle* is usually very correct in geographical matters. It has also been suggested that Zell most likely learned his art in Fust and Schoeffer's office and invented the passage to injure the reputation of Gutenberg, who had been their enemy. Finally it has been said that Zell did not suggest or write the passage at all; but it is hard to see how this can be maintained in face of the compiler's own statement to that effect. Therefore, all these sugges-

¹ In line 42 Gutenberg distinctly declares that "he hoped that he was under no obligation to Fust to devote the first 800 guilders to the work of the books;" and, as Fust, by advancing the second 800 guilders in 1452, had become Gutenberg's partner, it seems clear that the former claimed in 1454, when the trial is calculated to have commenced, his money and interest because Gutenberg had as yet not printed anything.

² Venit is the present not the perfect tense.

Lourens
Coster's
claims.

tions failing to weaken Zell's testimony, we must see how far it can be brought into harmony with other circumstances and the testimonies MM, RR, SS, TT, VV, XX, YY, which claim the honour of the invention for Haarlem in Holland. Testimonies RR and SS do not mention the name of the inventor. But the former is a mere introduction destined for a complete book that was lost during the siege of Haarlem in 1573 before it was printed; we are, therefore, not entitled to say that Van Zuren did not know the name. SS may have omitted the name, because the publication of Van Zuren's work was in contemplation at the time that it was written. That Guicciardini (testimony TT) in 1566 did not mention the name of the reputed Haarlem inventor cannot be considered as an indication that it was not known or had not yet been "invented" when he wrote, as his accounts of the cities of the northern Netherlands are all very meagre and were for the most part derived from correspondence. In Junius's account (VV), however, we find every particular that could be desired. He begins by referring to the difficulty of vindicating the honour of the invention for Haarlem on account of the deep-rooted and general opinion that it took place at Mainz. He then mentions that Lourens (son of Jan) surnamed Coster resided at Haarlem "more than 128 years ago" and gives us to understand that in the year indicated by that phrase he invented the art of printing. As Junius's book was not published till after his death, in 1588, and the two prefaces in it are dated 1575 (he died 16th June 1575), the number 128 is supposed to go back from the date when he actually wrote his account, which he is calculated to have done about 1568. Thus we get the year 1440 as the supposed date of the Haarlem invention, though, if we based our calculation upon the date of the preface, the year 1446 or 1447 would have to be assumed. But, as Junius adds that Coster's types were stolen by one of his servants, who fled with them to Mainz, and establishing there a printing office printed within a year's time, in 1442, two books, he must, if this latter date is correct, have meant 1440. By testimonies XX and YY we see that in the 17th century the date of the Haarlem invention was first put back as far as 1428, then to 1423; and since then it has usually been regarded as 1423, especially after it was discovered that the Haarlem wood where Coster is said to have cut his wooden letters was destroyed during a siege in 1426.

The researches as regards the reputed Haarlem inventor have hitherto not been made in a manner adequate for scientific purposes. It would appear that by the pushing back of the date of the invention, in spite of Junius, to 1420-1428, two inhabitants of Haarlem have been mixed up by the Dutch authors on the subject. (1) Lourens Janszoon, who never bore the surname Coster, and whose existence seems to be authenticated by documents from 1404 to 1439, was sheriff, and a wine merchant and innkeeper, and is supposed to have died in 1439. About 1870, however, researches brought to light that there had been (2) a Lourens Janszoon Coster at Haarlem, duly authenticated by genuine official documents as a chandler and innkeeper, from 1436 to 1483, who went away from Haarlem in the latter year. The name of this man and some genealogical particulars known of him fit into the story of Junius, though there are certain particulars in Junius's account which cannot yet be properly explained.

Junius bases his account of the Haarlem invention on three books, a Dutch edition of the *Speculum Humanæ Salvationis*, the *Doctrinale*, and the *Tracts* of Petrus Hispanus (Pope John XXI.). The first work, he said, was printed by Coster himself as a first specimen of his art, and it would seem from his words that he considered the work to be printed with wooden types. The two Dutch editions of the *Speculum*, however, were printed, like the two Latin editions of the same work, with movable metal type, though in one of the Latin editions there are twenty leaves the text of which is printed apparently from wooden blocks. The *Doctrinale* and the *Tracts* of Hispanus were printed, Junius says, at Mainz by Coster's workman with the types which he had stolen from Coster. Of the Hispanus *Tracts* no edition has yet come to light that would answer to Junius's description. But of the *Doctrinale* we have four editions, all printed in the same type (i.) as the four editions of the *Speculum*. With these same types are printed no less than six editions of the short Latin grammar of Ælius Donatus; and editions of this school-book printed in Holland were, according to Zell in the *Cologne Chronicle*, the models for the printing at Mainz, which commenced about 1450. As there are no other editions of Donatus printed in Holland that could be placed before the year 1450, the claims of Haarlem and Holland are based on them; and we will, therefore, briefly describe the types and books which must be connected with the *Specula*, *Doctrinalia*, and *Donatuses* just mentioned. In one of the editions of the *Speculum* in Dutch occur two leaves printed in a different type (ii.) from the rest of the work. This type is in its turn so very much like another type with which a work of Laur. Valla (*Facetie Morales*) is printed that we link it (iii.) on to the two just mentioned. Then again type iii. is, in some of its capitals, identical with a type (iv.) used for a work of Ludovicus de Roma, *Singularia Juris*, at the end of which, on the last leaf, commences another work, printed in a different type (v.).

Type vi. is identical with type v., except in its capital P, which is larger. We have also works printed in two different types (vii., viii.) which both show such a great family likeness to each other and to types i. to vi. that it would not be advisable to separate them without evidence that they do not belong to the same office. With these eight types, which we cannot at present separate, forty-seven different books were printed, so far as we know at present. In type i.:—four editions (two in Latin,¹ two in Dutch) of the *Speculum Humanæ Salvationis*, a work which consists of woodcuts with explanatory text underneath; a Dutch version of *The Seven Penitential Psalms*; one *Donatus* of 27 lines; two editions of *Donatus* of 28 lines; a *Liturgical Book* in 16mo; three editions of *Donatus* of 30 lines; one *Donatus*, in French, of 29 and 30 lines on a page; four editions of *Doctrinale* of 32 lines; one *Catonis Disticha* of 21 lines. In type ii.:—two leaves only (49 and 60) of one of the Dutch editions of the *Speculum*. In type iii.—Laurentius Valla, *Facetie Morales*, &c. In type iv.:—four editions of *Donatus* of 24 lines; Lud. (Pontanus) de Roma, *Singularia Juris*; Lud. (Pontanus) de Roma (?), *Treatise on Canonical Law* (?). In type v.:—Pius II., *Tractatus et Epitaphia* (printed at the end of the *Singularia Juris*); Guil. de Saliceto, *De Salute Corporis*; one *Donatus* of 26 lines; five editions of *Donatus* of 27 lines; one *Doctrinale* of 26 lines; one *Doctrinale* of 28 lines; one *Doctrinale* of 29 lines; one *Doctrinale* of 32 lines; *Catonis Disticha*; Guil. de Saliceto, *De Salute Corporis*, together with Turrecremata, *De Salute Animæ*; Pius II., *Tractatus de Amore*, &c.; Pindar of Thebes, *Iliados Homericæ Epitome, cum Præfatione Pii II.*; another edition of the same work. In type vi.:—one *Donatus* of 26 lines; one *Donatus* of 27 lines. In type vii.:—one *Donatus* of 27 lines. In type viii.:—an *Abecedarium* of two leaves and a *Donatus* of 31 lines.²

Type v. must have been in existence before 13th September 1474, as there is evidence that a copy of the *Saliceto*, printed in that type, was bought for the monastery of St James at Lille by its abbot Conrad du Moulin, who filled that office from the end of 1471 to 13th September 1474. As a work in this type (the *Tracts and Epitaphs* of Pius II.) is printed at the end of the *Singularia Juris* in type iv., we may assume that this type existed a considerable time before type v. As the books printed in types iv. and v. show greater progress in style and workmanship than the books printed in types i. to iii., we must assign the latter to an earlier period than the former. There is indeed positive evidence that type i. must have existed a considerable time before the end of 1473, as fragments of a *Donatus* printed in that type were used by a book-binder at Haarlem to strengthen the binding of an account-book of the cathedral church in that town for the year 1474. From these facts alone we may safely assume that none of the forty-seven books can be dated after 1474, or, if any, only a few in types v. and vii. On the other hand, four of the works in type v. cannot be dated before 1458, as they bear the name of Pius II., who was not elected pope till that year. When we consider that there are twenty different editions of the *Donatus* printed in these types, and place an interval of about eighteen months between the successive editions, we get a period of some thirty years from about 1445 to 1474 for the issue of the twenty editions. That we reach the year 1445 by such a calculation is purely accidental; but there is evidence that in 1446 and 1451 printed³ *Doctrinalia* were bought at Bruges and Valenciennes by Jean Le Robert, the abbot of Cambrai, according to two entries in his diary, preserved in the archives at Lille. And, as we know positively that there was no printing done at Mainz before 1454, nor anywhere else so early, we can only apply these entries to the *Doctrinalia* printed in Holland in the same types as the four editions of the *Speculum* (on which Junius based the tradition of the Haarlem invention), and six editions of the *Donatus*, which we may fit into Zell's account. That the editions of the *Speculum*, of the *Donatus*, and of the *Doctrinale* in type i. may be dated as early as 1445-1454 is clear when we compare them with the earliest products of Mainz printing, for which the *Donatuses*, according to the *Cologne Chronicle*, served as models. For instance, no difference in workmanship can be detected between the *Donatuses* printed in Holland and the three editions of *Donatus* in the 36-line Bible type and the four editions of the same in the 42-line Bible type, all seven presumably printed at Mainz and before 1456. Nor is the workmanship of the *Specula* (in type i.) or of the *Facetie Morales* (in type iii.) different from or later than that of the Mainz *Catholicon* of 1460.

It has been pointed out above that the first products of the art of printing were not meant to be anything but faithful imitations of manuscript books, and that no material deviations from the general plan become observable till about 1473-1477. Nowhere is the plan of the MS. period more strictly adhered to than in the

¹ Twenty leaves of one of the Latin editions are apparently printed from wooden blocks, the text as well as the engravings.

² For a detailed list of these books, and further particulars regarding them, see J. H. Hessels, *Haarlem, the Birthplace of Printing*, London, 1887, p. 25 sq.

³ The abbot speaks of *Doctrinalia* "gette" or "jetzet en molle," and the phrase is, as Bernard (*Origine*, l. 97 sq.) shows by eight examples from 1474—the year when printing is first officially spoken of in France—to 1593, and down to the present day, applied to typographically-printed books only.

Early
Dutch
types.

forty-seven books of which we are speaking. They are all without signatures, without initial directors, without hyphens, without catchwords, that is to say, without any of those characteristics which we see gradually, one after the other, come into almost general use from 1473 (if not earlier) to 1480. The four editions of the *Speculum* are all entirely printed anopisthographically, the woodcuts at the top of the pages as well as the explanatory text (in type i.) underneath, which would hardly be the case if the books had been printed after 1471, when the printing of woodcuts, together with text in movable types, had already been known for eleven years. Their types have nothing in common with any of those used in the Netherlands after 1473, but remind us in every respect of the earlier period of the Dutch block-books and MSS. They are all, so far as we know, without any colophon (except such a word as *explicit*), which would, for a collection of forty-seven books, be incompatible with a period after 1471, but not with the earlier period of the block-books and MSS. Moreover, out of the forty-seven books no less than thirty-five are printed on vellum, which is incompatible with a period after 1471, when printing on paper had become universal, but not with the earlier period of the MSS.

There is, therefore, no reason whatever to discredit Zell's statement in the *Cologne Chronicle* of 1499, that the *Donatuses* printed in Holland were the models, the "beginning" of the art of printing, at Mainz, nor that of Hadrianus Junius in his *Batavia*, that printing was invented at Haarlem by Lourens Janszoon Coster. The two statements were made independently of each other. That of Zell must be regarded as a direct contradiction of the vague rumours and statements about an invention of printing at Mainz in Germany by Gutenberg, which gradually crept into print in and after 1468 in Italy and France, and which found their way into Germany about 1476, after Mainz and Germany had given the greatest publicity to the existence of the art in their midst for more than twenty-two years, but had been silent about an invention and an inventor. And, though Zell accords to Mainz the honour of having improved the art and having made it more artistic, he denies it the honour of having invented or begun it, and this latter honour was never claimed by that town before 1476. Junius's account is the embodiment of a local tradition at Haarlem, the first written traces of which we have in a pedigree (testimony MM) of the family of the reputed Haarlem inventor, which must have existed at least as early as 1520. His account has been indirectly confirmed by the finding of several fragments at Haarlem, all belonging to the groups of books mentioned above, but still more by the discovery of several fragments of the *Donatuses* printed in the *Speculum* type, all used as binder's waste by Cornelis, the book-binder, the very man whom Junius alleges to have been the servant of Coster. As the case stands at present, therefore, we have no choice but to say that the invention of printing with movable metal types took place at Haarlem about the year 1445 by Lourens Janszoon Coster.

Early Types and their Fabrication.

We must now take notice of two theories or traditions which have been current for a long time as to some intervening stage between the art of block-printing and the art of printing with movable cast types.¹ One theory or tradition would have it that the inventor of printing, after the idea of single, individual, movable types had arisen in his mind, practised his new invention for some considerable time with wooden types, and that he came only gradually to the idea of movable types cast of metal.

Junius gives us to understand that in his opinion the Dutch *Speculum* was printed with such wooden types. Of Johann Gutenberg it was asserted that he printed his first Bible with wooden types. The Mainz psalter, printed in 1457 by Joh. Fust and Peter Schoeffer, was alleged to have been printed with wooden types, in which case the 4th edition, published in 1502, and even the 5th edition of 1516, would be printed with wooden types, the same being used for them as for the editions of 1457 and 1459. Theod. Bibliander was the first to speak (in 1548) of such types and to describe them: first they cut their letters, he says, on wood-blocks the size of an entire page; but, because the labour and cost of that way was so great, they devised movable wooden types, perforated and joined one to the other by a thread.² Bibliander does not say that he had ever seen such types himself, but Dan. Speckle or Specklin (died 1589), who ascribed the invention to Mentelin, asserts that he saw some of these wooden types at Strasburg.³ Angelo

Roccha asserted in 1591 that he had seen at Venice types perforated and joined one to the other by a thread, but he does not say whether they were of wood or of metal.⁴ In 1710 Paulus Pater asserted that he had seen wooden types made of the trunk of a box-tree, and perforated in the centre to enable them to be joined together by a thread, originating from the office of Fust at Mainz.⁵ Bodman, as late as 1781, saw the same types in a worm-eaten condition at Mainz; and Fischer stated in 1802 that these relics were used as a sort of token of honour to be bestowed on worthy apprentices on the occasion of their finishing their term.

Besides those who believed in these wooden types from the fact that the letters (especially in the *Speculum*) vary among themselves in a manner which would not be the case had they been cast from a matrix in a mould, there were authors and practical printers who attempted to cut themselves or to have cut for them some such wooden types as were alleged to have been used by the early printers. Some of them came to the conclusion that such a process would be quite practicable; others found by experiment that it would, in the case of small types, be wholly impossible. Up to the present time no book or document has come to light which can be asserted to have been printed with such single, movable, wooden types. But nearly all the experiments to which we have alluded were made with the idea that the inventor of printing, or the earliest printers, started, or had to start, with as large a supply of type as a modern printer. This idea is erroneous, as it is hardly any longer denied that, for a good many years after the first appearance of the art, printers printed their books (large or small) not by quires (quaternions or quinternions) but page by page.⁶ Therefore, all considerations of the experimenters as to the impracticability of such wooden types, on account of the trouble and length of time required for the cutting of thousands of types, fall to the ground in face of the fact that the earliest printers required only a very small quantity of type, in spite of the peculiar forms (combined letters, letters with contractions, &c.) which were then in vogue.

The other theory would have it that between block-Sculpto-printing and printing with movable cast types there was ^{fusi} an intermediate stage of printing with "sculpto-fusi" types, ^{types,} that is, types of which the shanks had been cast in a quadrilateral mould, and the "faces," i.e., the characters or letters, engraved by hand afterwards. This theory was suggested by some who could not believe in wooden types and yet wished to account for the marked irregularities in the types of the earliest printed books.

Gerardus Meerman, the chief champion of this theory, based it, not only on the words of Celtes (*Amores*, iii. 3), who in 1502 described Mainz as the city "quæ prima sculpsit solidos ære characteres," but on the frequent recurrence of the word *sculptus* in the colophons of the early printers (for Jenson and Husner of Strasburg, see p. 681 above). Sensenschmid in 1475 said that the *Codex Justinianus* was "cut" (*insculptus*), and that he had "cut" (*sculpsit*) the work of Lombardus, *In Psalterium*. Meerman also explained the account of the invention of printing by Trithemius⁷ as meaning that, after the rejection of the first wooden types, the inventors discovered a method of casting the bodies only of all the letters of the Latin alphabet from what they called matrices, on which they cut the face of each letter; and from the same kind of matrices a method was in time discovered of casting the complete letters of sufficient hardness for the pressure they had to bear, which letters they were before—that is, when the bodies only were cast—obliged to cut.⁸ In this way Meerman explained that the *Speculum* was printed in sculpto-fusi types, although in the one page of which he gives a facsimile there are nearly 1700 separate types, of which 250 alone are e's. Schoepflin claimed the same invention for Strasburg, and believed that all the earliest books printed there were produced by this means. Both Meerman and Schoepflin agreed that engraved metal types (*literæ in ære sculptæ*) were in use for many years after the invention of the punch and matrix, mentioning among others so printed the Mainz psalter, the *Catholicon* of 1460, the Eggstein Bible of 1468, and even the *Præceptorium* of Nider, printed at Strasburg in 1476. But the great difficulty connected with the process of first casting the shanks and afterwards engraving the faces of the types has become apparent to those who have made experiments; and it seems more probable that the terms *sculpere*, *exsculpere*, *insculpere* are only a figurative allusion to the first process towards producing the types, namely, the cutting of the punch, which is artistically more important to the fabrication of types than the mechanical casting,—all the more as Schoeffer in 1468 makes his *Grammatica Vetus Rhythmica* say, "I am cast at

¹ We do not allude to Trithemius's assertion that the *Catholicon* of 1460 was printed from wooden blocks; for this story, which he declares he had heard from Peter Schoeffer, if it were true, would belong to the history of block-printing. Nor need we speak of Bergellanus's verses (1541), in which he distinctly alludes to carved blocks.

⁷ *Annales Hirsaugienses*, ii. 421: "Post hæc inventis successerunt subtiliora, inveniturque modum fundendi formas omnium Latini alphabeti literarum, quas ipsi matrices nominabant, ex quibus rursus æneis sive stanneis characteres fundebant, ad omnem pressuram sufficientes, quos prius manibus sculpebant."

⁸ *Origines Typographicæ*, The Hague, 1765, Append., p. 47.

Mainz," an expression which could hardly be anything but a figurative allusion to the casting of the types.

Granting that all the earlier works of typography preserved to us are impressions of cast-metal types, there are still differences of opinion, especially among practical printers, as to the probable methods employed to cast them. It is considered unlikely that the inventor of printing passed all at once to the perfect typography of the punch, the matrix, and the mould. Bernard¹ considered that the types of the *Speculum* were cast in sand, as that art was certainly known to the silversmiths and trinket-makers of the 15th century; and he accounts for the varieties observable in the shapes of various letters on the ground that several models would probably be made of each letter, and that the types, when cast by this imperfect mode, would require some touching up or finishing by hand. He exhibits a specimen of a word cast for him by this process which not only proves the possibility of casting types in this manner but also shows the same kind of irregularities as those observable in the types of the *Speculum*.

But here again it is argued that in types cast by this or any other primitive method there would be an absence of uniformity in what founders term "height to paper." Some types would stand higher than others, and the low ones, unless raised, would miss the ink and not appear in the impression. The comparative rarity of faults of this kind in the *Speculum* leads one to suppose that, if a process of sand-casting had been adopted, the difficulty of uneven heights had been surmounted either by locking up the forme face downwards, or by perforating the types either at the time of casting or afterwards, and holding them in their places by means of a thread or wire. To this cause Otley attributed the numerous misprints in the *Speculum*, to correct which would have involved the unthreading of every line in which an error occurred. And, as a still more striking proof that the lines were put into the forme one by one, in a piece, he shows a curious printer's blunder at the end of one page, where the whole of the last reference-line is put in upside down, thus:—

Doe buag bespot slapende ende niet buetende.

④ *Deutsches Institut für Kapital.*

A "turn" of this magnitude could hardly have occurred if the letters had been set in the forme type by type.

Another suggested mode is that of casting in clay moulds, by a method very similar to that used in the sand process, and resulting in similar peculiarities and variations in the types.

Ottley, who was the chief exponent of this theory, suggested that the types were made by pouring melted lead or other soft metal into moulds of earth or plaster, after the ordinary manner used from time immemorial in casting statues of bronze and other articles of metal. But the mould thus formed could hardly avail for a second casting, as it would be scarcely possible to extract the type after casting without breaking the clay, and, even if that could be done, the shrinking of the metal in cooling would be apt to warp the mould beyond the possibility of further use. Ottley therefore suggests that the constant renewal of the moulds could be effected by using old types cast out of them, after being touched up by the graver, as models,—a process which he thinks will account for the varieties observable in the different letters, but which would really cause such a gradual deterioration and attenuation in the type, as the work of casting progressed, that in the end it would leave the face of the letter unrecognizable as that with which it began. It would therefore be more reasonable to suppose that one set of models would be used for the preparation of all the moulds necessary for the casting of a sufficient number of types to compose a page, and for the periodical renewal of the moulds all through the work, and that the variations in the types would be due, not to the gradual paring of the faces of the models, but to the different skill and exactness with which the successive moulds would be taken. It is evident that the sand and clay methods of casting types above described must be slow. The time occupied after the first engraving of the models in forming, drying, and clearing the moulds, in casting, extracting, touching up, and possibly performing the types required for one page, would exceed the time required by a practised xylographer for the cutting of a page of text upon a block. But he that has gone through the trouble of casting separate movable types has a clear gain over the wood-block printer in having a fount of movable types, which, even if the metal in which they were cast were only soft lead or pewter, might be used again and again in the production of any other page of text, while the wood-block can only produce the one page which

it contains. Moreover, only one hand could labour on the xylographic block; but many hands could be employed in the moulding and casting of types, however rude they might be. Bernard states that the artist who produced for him the few sand-cast types shown in his work assured him that a workman could easily produce a thousand such letters a day. He also states that, though each letter required squaring after casting, there was no need to touch up the faces.

There remains yet another suggestion as to the method Poly- in which the types of the rude school may have been ^{type} produced. This may be described as a system of what the founders of sixty years ago called polytype, which is a cast or facsimile copy of an engraved block, matter in type, &c.

Lambinet,² who is responsible for the suggestion, based upon a new translation of Trithemius's narrative, explains that this process really means an early adoption of stereotype. He thinks that the first printers may have discovered a way of moulding a page of some work—an *Abecedarium*—in cooling metal, so as to get a matrix-plate impression of the whole page. Upon this matrix they would pour a liquid metal, and by the aid of a roller or cylinder press the fused matter evenly, so as to make it penetrate into all the hollows and corners of the letters. This tablet of tin or lead, being easily lifted and detached from the matrix, would then appear as a surface of metal in which the letters of the alphabet stood out reversed and in relief. These letters could easily be detached and rendered mobile by a knife or other sharp instrument, and the operation could be repeated a hundred times a day. The metal faces so produced would be fixed on wooden shanks, type high, and the fount would then be complete. Lambinet's hypothesis was endorsed by Firmin-Didot, the renowned type-founder and printer of Lambinet's day. But it is impossible to suppose that the Mainz psalter of 1457, which these writers point to as a specimen of this mode of execution, is the impression, not of type at all, but of a collection of "casts" mounted on wood.

Whatever value there may be in the above theories with Shape of regard to the movable types of the first printer, certain it ^{earliest} is that the shape and manufacture of the types used ^{type} as early as c. 1470 do not seem to have differed materially from those of the present types.

This is evident (1) from the shape of the old types which were discovered in 1878 in the bed of the river Saône, near Lyons, opposite the site of one of the 15th-century printing houses of that city, and which there is reason to believe belonged once to one of those presses, and were used by the early printers of Lyons; (2) from a page in Joh. Nider's *Lepra Moralis*, printed by Conrad Homburch at Cologne in 1476, which shows the accidental impression of a type, pulled up from its place in the course of printing by the ink-ball, and laid at length upon the face of the forme, thus leaving its exact profile indented upon the page; (3) from an entirely similar page (fol. 4^b) in *Liber de Laudibus ac Festis Gloriosæ Virginis*, Cologne, c. 1468. From the small circle appearing in the two last-mentioned types, it is presumed that the letters were pierced laterally by a circular hole, which did not penetrate the whole thickness of the letter, and served, like the nick of modern types, to enable the compositor to tell by touch which way to set the letter in his stick. The fact that in these two cases the letter was pulled up from the forme seems to show that the line could not have been threaded.

Vinc. Fineschi, *Notizie Storiche sopra la Stamperia di Ripoli* (Florence, 1781, p. 49), gives an extract from the cost-book of the Ripoli press, about 1480, by which it appears that steel, brass, copper, tin, lead, and iron wire were all used in the manufacture of types at that period.³

The history and nomenclature of the earliest types are practically a continuation of the history and nomenclature of the characters figured in the earliest block-books, wood-engravings, and MSS. For instance, Gothic type was first seen about the year 1445; but it should not be forgotten that the Gothic writing, of which that type was an imitation, was already known and used about the second half of the 12th century. Again, the pure Roman type, which appeared about 1464, is nothing but an imitation of what in palæography is called the Caroline minuscule, a handwriting which was already fully developed towards the end of the 8th century. Consequently, details as to the history and development of the various types properly belong to the study of PALÆOGRAPHY (*q.v.*).

² *Origine de l'Imprimerie*, Paris, 1810, 2 vols. 8vo, i. 97.

Types
cast in
sand.

Types
cast in
clay
moulds.

The broad outlines of the history of the earliest types are as follows:—

Gothic.

Gothic type, of the angular or pointed kind, was first used by the Haarlem printer of the *Speculum*, *Donatus*, &c. (see specimen No. 1, taken from the British Museum copy of the *Speculum Humanæ Salvationis*, mixed Latin edition), presumably c. 1445. An entirely similar but larger type (No. 2, taken from the British Museum copy of Ludovicus [Pontanus] of Roma, *Singularia*) was used, presumably by the same printer, c. 1465-1470. Gothic type appeared in Germany as a church type in 1454, in the 31-line indulgence, presumably printed by Johan Gutenberg at Mainz (No. 3, from the Göttingen copy), and in the 30-line indulgence (No. 4, taken from the British Museum copy), printed by Peter Schoeffer at Mainz. Type No. 3 was also used about the same time for the 36-line Bible and type No. 4 for the 42-line Bible. Two much larger Gothic types appeared in the psalter of 1457, published by Fust and Schoeffer (see Bernard, *Origine*, pl. vii.). In Italy Gothic type appears in 1468 (No. 5, taken from the British Museum copy of Cicero, *De Oratore* published at Rome by Ulr. Hahn, 15th December 1468, in small Roman type, with imprint in Gothic), but in a more rounded form; it is practically the ordinary Italian writing influenced by the Gothic. In France Gothic began to be used in 1473; in England it appears first in Caxton's type about the year 1480.¹ It was employed extensively in a great many of the earliest presses all over Europe, and continued to be used largely at all times, especially for Bibles, law books, royal proclamations, &c., and even to this day it is the national character of Germany. It is now usually called *lettre de forme*, *black letter* or *English* in English-speaking countries, *lettre Flamand* in Holland, and *fraktur* in Germany.

Bastard Italian or Roman.

Bastard Italian or bastard Roman was introduced in 1454 at Mainz in the 31-line (No. 6) and 30-line (No. 7) indulgence. It is also called *lettre de somme*, some think from the *Summa* of Thomas Aquinas, printed in the type of the Bible of 1462 by Fust and Schoeffer. Varieties of this kind of type were, like the Gothic, much used by the earliest printers, as, for instance, the printer of the 1460 *Catholicon*, i.e., by Mentelin of Strasburg, c. 1460, and by Ulrich Zell at Cologne, c. 1466, &c. In England it appeared in the first three books printed (1478, 1479) at Oxford (No. 8, taken from the British Museum copy of Jerome's *Expositio in Simbolum Apostolorum*, wrongly dated 1468 for 1478).

Roman.

Roman type, the Caroline minuscule of palæography, was first used in Germany about 1464, at Strasburg, by the printer whose fount of type is known by a peculiarly shaped R, and who on that account is usually called "the R printer" (No. 9, taken from the British Museum copy of Durandus, *Rationale*, of which the Basel library possesses a copy which was bought in 1464).² In Italy it appears in 1465 at Subiaco (see Bernard, pl. xii., No. 19), at Rome in 1467 (*op. cit.*, pl. xii., No. 20), but in all its purity at Venice in 1469, used by Johannes of Spire (see Bernard, pl. xii., No. 23), and at Paris in 1470 (*op. cit.*, pl. xiii., No. 25). In England it was not used before 1518, when Richard Pynson printed Pace's *Oratio in Pace Nuperrima* (see facsimile in Reed's *Type Foundries*, p. 92).

Burgundian.

Burgundian type, or *gros batarde* or *secretary*, was first used about 1470-72 by Colard Mansion at Bruges (No. 10, taken from the British Museum copy of *La Controverſie de Noblesse*, c. 1471-72). With a somewhat similar type (No. 11, taken from the British Museum copy of the *Recuyell*) William Caxton is presumed to have printed, likewise at Bruges, a set of five books, of which the *Recuyell of the History of Troye*, a translation of a work by Raoul le Fèvre, is the best known and was probably printed c. 1471.³ To this same class belong the first type (No. 12, from the British Museum copy of the *Dictes*) used in England by William Caxton for the printing of *Dictes and Sayings of the Philosophers* (18th November 1477), and that used by the printer of St Albans (No. 13, taken from the Cambridge university library copy of Aug. Dactus, *Elegancie*). It

was an imitation of the manuscript hand of the English and Burgundian scribes of the 15th century, and, after having figured for a long time in several of the early London and provincial presses, was about 1534 entirely superseded by the English black letter. To this class of type belong also the later *lettre de civilité* (c. 1570), the *script* (*lettre coulée*, *lettre de finance*, Dutch *geschreven schrift*), *set court*, *base secretary*, and *running secretary* types.

On the types before 1500, consult also the facsimiles in Holtrop's *Mon. Typ. des Pays-Bas*, The Hague, 1868; R. C. Hawkins, *First Books and Printers of the Fifteenth Century*, New York, 1884; William Blades, *The Life of Caxton*, London, 1861-63; Bernard, *Origine de l'Imprimerie*, Paris, 1853, vol. i., plates iii.-xiii.; Placidus Braun, *Notitia de Libris ab Artis Typogr. Inventionis usque ad Annum 1479 Impressis*, Augsburg, 1788; H. Noel Humphreys, *Hist. of the Art of Printing*, fol., London, 1867. The types after 1500 can best be learned from the catalogues of type-founders, among which those of Messrs. Enschedé of Haarlem occupy a foremost place. Of others we may mention—*Indice dei Caratteri nella Stampa Vaticana*, 4to, Rome, 1628; *Epreuves des Caractères qui se trouvent chez Claude Lameste*, 4to, Paris, 1742; *Epreuves des Car. de la Fonderie de Claude Moret*, Svo, Nantes, 1754; *Les Car. de l'Imprimerie par Fournier le Jeune*, Svo, Paris, 1764; *Proef van Letteren, Bloemen, &c. van Ploos van Amstel*, Svo, Amsterdam, 1767; *Epreuue de Car. de Jacques François Rosart*, Svo, Brussels, 1771; *Schriften . . . bey J. H. Prentzler*, 4to, Frankfurt-on-Main, 1774; *Epreuves des Car. de la Fond. de J. L. Joannis*, Svo, Paris, 1776; *Epreuves des Car. de la Fond. de J. de Bouchers*, Svo, Brussels, 1777; *Proeve van Letteren welke gegooten worden door J. de Groot*, Svo, The Hague, 1787; *Pantographie*, by Edmund Fry, Svo, London, 1799; and *Manuale Typographicum*, by G. Bodoni, 4to, Parma, 1818.

Subsequent to 1500.

Though the *Cologne Chronicle* of 1499 denies to Mainz Printers the honour of the invention of the art of printing, it was after right in asserting that, after it had been brought there from Holland, it became much more masterly and exact, and more and more artistic. During the first half century of printing a good many printers distinguished themselves by the beauty, excellence, and literary value of their productions. We may mention as such:—Johan Fust and Peter Schoeffer at Mainz; Johan Mentelin and Heinrich Eggestein at Strasburg; Ulrich Zell at Cologne; Sweynheym and Pannarts at Subiaco and at Rome; Nicolas Jenson at Venice; Anton Koberger at Nuremberg; Kete-laer and De Leempt at Utrecht; Johan Veldener at Louvain, Utrecht, and Kuilenburg; Gerard Leeu at Gouda; Johan of Westphalia at Louvain; and William Caxton (q.v.) at Westminster.

Very soon the demand for books increased, and with it came a reduction in their prices. This caused a decline in the execution of printing, which begins to be appreciable about 1480 in some localities, and may be said to have become general towards the end of the 15th century. At all times, however, we find some printers raise their art to a great height by the beauty of their types and the literary excellence of their productions. Among the later printers we may mention the Aldi of Venice (1490 to 1597; see

MANUTIUS, vol. xv. p. 512); G. B. Bodoni of Parma (1768-1813; see vol. iii. p. 849); John Amerbach at Basel (1492-1516); John Froben at Basel (1496-1527; see vol. ix. p. 791); John Baskerville at Birmingham (1750-1775; see vol. iii. p. 421); the house of Wechel, first at Paris (c. 1530-1572), afterwards at Frankfurt; Christopher Plantin at Antwerp (1554-1589), but continued long after under the firm *Officina Plantiniana* (see vol. xix. p. 176); the Elzevirs, first at Leyden, afterwards at Amsterdam (1580-1680; see vol. viii. p. 156); Antoine Verard at Paris (1485-1513); Josse Bade at Paris (1495-1535; see BADIUS, vol. iii. p. 228); and the Estiennes at Paris (1502-1598; see STEPHENS, vol. xxii. p. 534).

History of Modern Types.

Italic.

The Italic type¹ is said to be an imitation of the handwriting of Petrarch, and was introduced by Aldus Manutius of Venice for the purpose of printing his projected small editions of the classics. The cutting of it was entrusted to Francesco da Bologna, an artist who is presumed to be identical with the painter Francesco Francia or Raibolini. The fount is a "lower case" only, the capitals being Roman in form. It contains a large number of tied letters, to imitate handwriting, but is quite free from contractions and ligatures. It was first used in the *Virgil* of 1500. Aldus produced six different sizes between 1501 and 1558. It was counterfeited almost immediately in Italy, at Lyons, and elsewhere. Originally it was called Venetian or Aldine, but subsequently Italic type, except in Germany and Holland, where it is called "cursive." The Italians also adopted the Latin name "characteres cursivi seu cancellarii." In England it was first used by Wynkyn de Worde in Wakefield's *Oratio* in 1524. The character was at first intended and used for the entire text of classical works. When it became more general, it was employed to distinguish portions of a book not properly belonging to the work, such as introductions, prefaces, indexes, notes, the text itself being in Roman. Later it was used in the text for quotations, and finally served the double part of emphasizing certain words in some works, and in others, chiefly translations of the Bible, of marking words not rightly forming a part of the text.

Greek.

Greek type (*minuscules*) first occurs in Cicero, *De Officiis* printed at Mainz in 1465 by Fust and Schoeffer. The fount used is rude and imperfect, many of the letters being ordinary Latin. In the same year Sweynheym and Pannarts used a good Greek letter for some of the quotations in their edition of *Lactantius* (see, for instance, leaves 11a, 19a, 36a, 139, 140); but the supply was evidently short at first, as some of the larger quotations in the first part of the book were left blank to be filled in by hand. The first book wholly printed in Greek minuscules was the *Grammar* of Lascaris, by Paravisinus, at Milan in 1476, in types stated to have been cut and cast by Demetrius of Crete. The fount contains breathings, accents, and some ligatures. The headings to the chapters are wholly in capitals. The *Anthologia Græca* of Lascaris was printed at Florence in 1494 wholly in Greek capitals (*litteræ majusculæ*), and it is stated in the preface that they were designed after the genuine models of antiquity to be found in the inscriptions on medals, marbles, &c. But as late as 1493 Greek type was not common, for in that year the Venice printer Symon Bevilacqua issued *Tibullus*, *Catullus*, and *Propertius* with blanks left in the commentary for the Greek quotations. In England Greek letters appeared for the first time in 1519 in W. de Worde's edition of Whitenton's *Grammatica*, where a few words are introduced cut in wood. Cast types were used at Cambridge in Galen's *De Temperamentis*, translated by Linacre, and printed by Siberch in 1521, who styles himself the first Greek printer in England; but the quotations in the Galen are very sparse, and Siberch is not known to have printed any entire book in Greek. The first printer who possessed Greek types in any quantity was Reginald Wolfe, who held a royal patent as printer in Greek, Latin, and Hebrew, and printed in 1543 two *Homilies* of Chrysostom, edited by Sir John Cheke, the first Greek lecturer at Cambridge. In Edinburgh, in 1563, and as late as 1579, the space for Greek words was left blank in printing, to be filled in by hand. In 1632 Cambridge applied to Oxford for the loan of a Greek fount to print a Greek Testament, and the same university made an offer in 1700 for the purchase of a fount of the king's Greek at Paris, but withdrew on the French Academy insisting as a condition that every work printed should bear the imprint "characteribus Græcis e typographeo regio Parisiensis." It should not be forgotten that the large number of ligatures in the Greek of that day made the production of a fount a serious business. The Oxford Augustin Greek comprised no fewer than 354 matrices, the

great primer 456, and even one fount showed 776 different sorts. The Dutch founders effected a gradual reduction of the Greek typographical ligatures. Early in the 19th century a new fashion of Greek, for which Porson was sponsor and furnished the drawings, was introduced, and has remained the prevailing form to this day.

The first Hebrew types are generally supposed to have appeared Hebrew. in 1475 in Petrus Niger's *Tractatus contra Perfidios Judæos* (leaf 10), printed by Conrad Fyner at Esslingen. De Rossi states that a Hebrew work in four folio volumes entitled *Arba Turim* of Rabbi Jacob ben Asher, was printed in 1475 at Pieve di Sacco in Austrian Italy, while in the same year, a few months earlier, Salomon Jarchi's *Comment. on the Pentateuch* appeared at Reggio in Italy, printed in the Rabbinical character. Numerous other Hebrew works followed before 1483, in which year the first entire Hebrew Bible was printed, with points, at Soncino, by a family of German Jews. The first English book in which any quantity of Hebrew type was used was Dr Rhys's *Cambro-Brytannicæ Cymræcæ Lingvæ Institutiones*, printed by Thomas Orwin in 1592, though already in 1524 Hebrew characters, but cut in wood, were used by W. de Worde in Wakefield's *Oratio*. But the Hebrew fount made use of in Walton's *Polyglott* in 1657 was probably the first important fount cut and cast in England, though there were as yet no matrices there for Rabbinical Hebrew. In the beginning of the 18th century Amsterdam was the centre of the best Hebrew printing in Europe.

The first book printed in Arabic types is said to be a *Diurnale Arabicæ Græcorum Arabum*, printed at Fano in Italy in 1514.² Two years later P. P. Porrus's *Polyglott Psalter*, comprising the Arabic version, was printed at Genoa; and two years later a *Koran* in Arabic is said to have been printed at Venice. In 1505 an *Arabic Vocabulary* at Granada had the words printed in Gothic letters with the Arabic points placed over them; and in other presses where there were no Arabic types the language was expressed in Hebrew letters or cut in wood. De Guignes and others mention a fount of Arabic used by Gromors in Paris in 1539-40 to print Postel's *Grammar*. In England some Arabic words were introduced in Wakefield's *Oratio* of 1524, but apparently cut in wood. In Minshew's *Ductor in Linguas*, 1617, the Arabic words are printed in Italic characters. Laud's gift of Oriental MSS. to Oxford in 1635, and the appointment of an Arabic lecturer, were the first real incentives to the cultivation of the language by English scholars. Previous to this it is stated that the Raphelengius Arabic press at Leyden had been purchased by the English Orientalist, William Bedwell; but, if it was brought to England, it does not appear to have been immediately made use of. The Arabic words in Thomas Greave's *Oratio de Lingvæ Arabicæ Utilitate*, printed at Oxford in 1639, were written in by hand.

Syriac type, probably cut in wood, first appeared in Postel's *Syriacæ Linguarum XII. Alphabetæ*, printed in Paris in 1538; but the characters are so rude in form and execution as to be scarcely legible. In 1555, however, Postel assisted in cutting the punches for the Syriac Peshito New Testament, printed at Vienna in 4to, the first portion of the Scriptures, and apparently the first book, printed in that language. In 1569-72 Plantin at Antwerp included the Syriac New Testament in his *Polyglott*, and reissued it in a separate form in 1574. In England Syriac was usually expressed in the earlier works in Hebrew characters. But in 1652, when the prospectus and preliminary specimen of Walton's *Polyglott* were issued, we find Syriac type in use.

Of the Armenian character the press of the Vatican possessed a Armenian good fount in 1591, when Angelo Roccha showed a specimen in his *Bibliotheca Apostolica Vaticana*. A psalter is said to have been printed at Rome in 1565, and Rowe Mores mentions doubtfully a liturgy printed at Cracow in 1549. Armenian printing was practised in Paris in 1633; but the Armenian bishops, on applying to France for assistance in printing an Armenian Bible in 1662, were refused, and went to Rome, where, as early as 1636, the press of the Propaganda had published a specimen of its Armenian matrices. The patriarch, after fifteen months' residence in Rome, removed to Amsterdam, where he established an Armenian press, and printed the Bible in 1666, which was followed in 1668 by a separate edition of the New Testament. In 1669 the press was set up at Marseilles, where it continued for a time, and was ultimately removed to Constantinople. In England the first Armenian type was that presented by Dr Fell to Oxford in 1667. The alphabet given in the prolegomena of Walton's *Polyglott* was cut in wood.

Of Ethiopic the earliest type appeared in Potken's *Psalter and Ethiopic Song of Solomon*, printed at Rome in 1513. The work was reprinted at Cologne in 1518 in Potken's *Polyglott Psalter*. In 1548 the New Testament was printed at Rome by some Abyssinian priests. The press of the Propaganda issued a specimen of its fount in 1631, and again in Kircher's *Prodromus Coptus* in 1636. Erpenius at Leyden had an Ethiopic fount, which in 1626 was acquired by the Elzevirs. Usher attempted to procure the fount for England; but, his attempt failing, punches were cut and matrices prepared by the London founders for the London *Polyglott*, which showed the Psalms, Canticles, and New Testament in the Ethiopic version.

¹ These paragraphs on the various types are for the most part taken from T. B. Reed's *History of the Old English Letter Foundries*, London, 1887, p. 50 sq.

² See Panzer, vii. 2.

- Coptic.** Of Coptic the press of the Propaganda possessed a fount, and a specimen was issued in 1636, in which year also Kircher's *Prodromus Coptus* appeared from the same press. In England David Wilkins's edition of the New Testament was printed in 1716 from Coptic types cast with matrices which Dr Fell had presented to Oxford in 1667. The alphabets shown in the introduction and prolegomena to the London *Polyglott* of 1655 and 1657 were cut in wood.
- Samari-
tan.** Of Samaritan the press of the Propaganda had a fount in 1636, and the Paris *Polyglott*, completed in 1645, contained the entire Pentateuch in type the punches and matrices of which had been specially prepared under Le Jay's direction. The fount used for the London *Polyglott* in 1657 is admitted to have been an English production, and was probably cut under the supervision of Usher.
- Slavonic.** With Slavonic type a psalter was printed at Cracow as early as 1491, and reprinted in Montenegro in 1495. The only Slavonic fount in England was that given by Dr Fell to Oxford, and this, Mores states, was replaced in 1695 by a fount of the more modern Russian character, purchased probably at Amsterdam. The *Oratio Dominica* of 1700 gives a specimen of this fount, but renders the Hieronymian version in copper-plate. Modern Slavonic, better known as Russian, is said to have appeared first in portions of the Old Testament printed at Prague in 1517-19. Ten years later there was Russian type in Venice. A Russian press was established at Stockholm in 1625, and in 1696 there were matrices in Amsterdam, from which came the types used in Ludolph's *Grammatica Russica*, printed at Oxford in that year, and whence also, it is said, the types were procured which furnished the first St Petersburg press, established in 1711 by Peter the Great. Mores notes that in 1778 there was no Russian type in England, but that Cottrell was at that time engaged in preparing a fount. It does not appear that this project was carried out, and the earliest Russian in England was cut by Dr Fry from alphabets in the *Vocabularia*, collected and published for the empress of Russia in 1786-89. This fount appeared in the *Pantographia* in 1799.
- Etruscan.** A fount of the Etruscan character cut by William Caslon about 1733 for Swinton of Oxford was apparently the first produced. Fournier in 1766 showed an alphabet engraved in metal or wood. In 1771 the Propaganda published a specimen of their fount, and Bodoni of Parma in 1806 exhibited a third in his *Oratio Dominica*.
- Runic.** Runic types were first used at Stockholm in a Runic and Swedish *Alphabetarium*, printed in 1611. The fount, which was cast at the expense of the king, was afterwards acquired by the university. About the same time Runic type was used at Upsala and at Copenhagen. Voskens of Amsterdam had matrices about the end of that century, and it was from Holland that Francis Junius is supposed to have procured the matrices which in 1677 he presented to Oxford. This fount appears in the *Oratio Dominica* of 1700, and in Hickeys's *Thesaurus*, 1703-5, and it remained the only one in England.
- Gothic.** Matrices of Gothic type were presented to Oxford by Francis Junius in 1677, and a fount of them was used for the *Oratio Dominica* of 1700 and in Hickeys's *Thesaurus*. A different fount was used for Chamberlayne's *Oratio Dominica*, printed at Amsterdam in 1715. Caslon cut a fount which appeared in his first specimen in 1734. This and the Oxford fount were the only two in England in 1820.
- Scandi-
navian.** Founts of Icelandic, Swedish, and Danish were included in Junius's gift to Oxford in 1677, and were, perhaps, specially prepared in Holland. The first-named is shown in the *Oratio Dominica* of 1700 and in Hickeys's *Thesaurus*. Printing had been practised in Iceland since 1531, when a *Breviary* was printed at Hoolum, in types rudely cut, it is alleged, in wood. In 1574, however, metal types were provided, and several works produced. After a period of decline, printing was revived in 1773, and in 1810 Sir George M'Kenzie reported that the Hoolum press possessed eight founts of type, of which two were Roman, and the remainder of the common Icelandic character, which, like the Danish and Swedish, bears a close resemblance to the German.
- Anglo-
Saxon.** For the Anglo-Saxon language the first type was cut by John Day in 1567, under the direction of Archbishop Parker, and appeared in *Ælfrie's Paschal Homily* in that year and in the *Ælfredi Res Gestæ* of Asser Menevensis in 1574. Anglo-Saxon type was used by Browne in 1617, in Minshew's *Ductor in Linguas*; and Haviland, who printed the second edition of that work in 1626, had in 1623 made use of the character in Lisle's edition of *Ælfrie's Homily*.
- Irish.** The first fount of Irish character was that presented by Queen Elizabeth to O'Kearney in 1571, and used to print the Catechism which appeared in that year in Dublin, from the press of Franckton. But the fount is only partially Irish, many of the letters being ordinary Roman or Italic. It was used in several works during the early years of the 17th century, and as late as 1652 in Godfrey Daniel's *Christian Doctrine*, printed in Dublin. The Irish seminaries abroad were better supplied with Irish type. A new type was cut by Moxon, and appeared in 1681 in Boyle's New Testament, printed by Robert Everingham.
- Music.** The earliest specimen of music type occurs in Higden's *Polychronicon*, printed by De Worde at Westminster in 1495. The square notes appear to have been formed of ordinary quadrats, and the staff-lines of metal rules imperfectly joined. In Caxton's edition of the same work in 1482 the space had been left to be filled up by hand. The plain chant in the Mainz psalter of 1490, printed in two colours, was probably cut in wood. Hans Froschauer of Augsburg printed music from wooden blocks in 1473, and the notes in Burtius's *Opusculum Musices*, printed at Bologna in 1487, appear to have been produced in the same manner; while at Lyons the missal printed by Matthias Hus in 1485 had the staff only printed, the notes being intended to be filled in by hand. About 1500 a musical press was established at Venice by Ottavio Petrucci, at which were produced a series of mass-books with lozenge-shaped notes, each being cast complete with a staff-line. In 1513 he removed to Fossombrone, and obtained a patent from Leo X. for his invention of types for the sole printing of figurative song (*cantus figuratus*). Before 1550 several European presses followed Petrucci's example, and music type was used, among other places, at Augsburg in 1506 and 1511, Parma in 1526, Lyons in 1532, and Nuremberg in 1549. In 1525 Pierre Hautin cut punches of lozenge-shaped music at Paris. Round notes were used at Avignon in 1532. In England, after its first use, music-printing did not become general till 1550, when Grafton printed Marbecke's Book of Common Prayer, "noted" in movable type, the four staff-lines being printed in red and the notes in black. There are only four different sorts of notes used,—three square and one lozenge. About 1660 the detached notes hitherto employed began to give place to the "new tyed note," by which the heads of sets of quavers could be joined. But at the close of the 17th century music-printing from type became less common, on account of the introduction of stamping and engraving plates for the purpose.
- Printing for the blind (compare vol. iii. p. 826) was first introduced in 1784 by Valentin Haüy, the founder of the asylum for the blind children in Paris. He made use of a large script character, blind, from which impressions were taken on a prepared paper, the impressions being so deeply sunk as to leave their marks in strong relief and legible to the touch. Haüy's pupils not only read in this way, but executed their own typography, and in 1786 printed an account of their institution and labours as a specimen of their press. The first school for the blind in England was opened in Liverpool in 1791, but printing in raised characters was not successfully accomplished till 1827, when Gall of the Edinburgh asylum printed the Gospel of St John from angular types. Alston, the treasurer of the Glasgow asylum, introduced the ordinary Roman capitals in relief, and this system was subsequently improved upon by the addition of the lower-case letters by Dr Fry, the type-founder, whose specimen gained the prize of the Edinburgh Society of Arts in 1837. Several rival systems have competed in England for adoption, of which the most important are those of Lucas, Frere, Moon, Braille, Carton, and Alston; the last-named, as perfected by Dr Fry, seems likely to become the recognized method of printing for the blind in all European countries.
- As regards initials in the earliest printed books, see above, p. 686. **Initials.** The trouble and cost involved in the use of the initial director early suggested the use of wood-cut initials, and Erhard Ratdolt of Venice, about 1475, is generally supposed to have been the first printer to introduce the *litteræ florentes*, called also *litteræ tourneures*, or *typi tornatissimi*, which eventually superseded the hand-painted initials. Caxton introduced one or two kinds in 1484. Among the earliest to be used are the so-called Lombardic initials or capitals. The more elaborate initials, such as those used in the Mainz indulgences and psalter, by Aldus at Venice, by Johann Schoeffer at Mainz in 1518, by Tory and the Estiennes at Paris, by Froben at Basel, and by the other great printers of their day, were known as *litteræ grises*. Besides these, the ordinary "two-line letters" or large plain capitals came into use; and these were generally cast, whilst the ornamental letters were for the most part engraved on wood or metal.
- Type ornaments and flowers began, like the initials, with the Ornament-illuminators, and were afterwards cut on wood or metal. The first printed ornament or vignette is supposed to be the scutum or arms and of Fust and Schoeffer in their edition of the Bible of 1462. There flowers. is no vignette in the Subiaco *Lactantius* of 1465 (as stated by Mr Reed, *Letter Foundries*, p. 82). In Holtrop's *Monum. Typogr. des Pays-Bas* may be seen borders used by some of the earliest printers of Holland (1475-1490) which would not look bad even in the present time. Caxton in 1490 used ornamental pieces to form the border for his *Fifteen O's*. At the same time the Paris printers engraved still more elaborate border pieces. At Venice entire frames were engraved in one piece, while Aldus as early as 1495 used tasteful head-pieces cut in artistic harmony with his *litteræ grises*. Early in the 16th century we observe detached ornaments and flourishes which have evidently been cast from a matrix.
- Literature.*—Besides the works of Berjeau, Bernard, Blades, Hawkins, Hessels, Holtrop, Noel Humphreys, Koehler, Jules Philippe, T. B. Reed, Sotheby, Weigel, &c., already mentioned, consult also Bigmore and Wynan, *A Bibliography of Printing*, London, 1880; Geo. Wolff, Panzer, *Annales Typog.*, Nuremberg, 1798, &c.; Lud. Hain, *Repertorium Bibliog.*, Stuttgart, 1826-38; Holtrop, *Cat. Librorum Sec. XV^o Impressorum in Bibl. Regia Hagana*, The Hague, 1856; M. F. A. G. Campbell, *Ann. de la Typog. PART II.—PRACTICAL.

Definition.

Printing has been defined to be the act, art, or practice of impressing letters, characters, or figures on paper, cloth, or other material, the definition being based on the etymology (Old Fr. *empreindre*, from Lat. *imprimere*). Technically the same definition might be applied to such arts as those of calico and oilcloth printing, and even of moulding, embossing, coining, and stamping; but in point of fact these are never understood when the word "printing" is employed. There is also printing without pressure, such as photographic printing. The use of a pigment or ink must be regarded as an indispensable element. The application of the term is therefore confined to the use of pressure and a pigment for literary and pictorial purposes. As thus defined, printing includes three entirely different processes—not inaptly called the polygraphic arts—viz., chalcography or copperplate printing (compare ENGRAVING, vol. viii. p. 439 *sq.*), LITHOGRAPHY (*q. v.*) or chemical stone-printing, and typography or letterpress printing. The last-named is that to which the present article is confined.

Typography, chalcography, and lithography.

The difference between the three methods lies essentially in the nature or conformation of the surface that is inked, and which afterwards gives a reproduction or image in reverse on the material to be impressed. In copperplate printing the whole of a flat surface is inked, and a portion of the ink sinks into an incision or trench, in which it still remains after the surface is cleansed. When pressure is brought to bear, this ink is transferred to the paper, giving an impression of a line. In lithographic printing the flat surface is protected except at certain places, where it is slightly coated with the ink, which practically leaves the stone quite level, but also marks a line when pressure is brought to bear. In typography the printing surface is in relief. It alone receives ink, the remainder being protected by its lower level. Any kind of printing done from a relief surface belongs to letterpress printing, such as a woodcut, a casting in metal, india-rubber, celluloid, xylonite, &c. (or "stereotype"), or a deposition by electricity (or "electrotype"). The typographic method requires a surface that is more difficult to form than either of the other two. In lithography the surface may be obtained by merely writing or drawing on the stone; in copperplate printing the line may be immediately incised into or scratched on the plate; but for letterpress printing the surface between the lines in relief has to be cut away. Hence the tediousness of wood-engraving, in which all the surface of the block has to be removed except those parts that are to be printed from and which form the black lines in the impression; and the conformation of a type surface is similar.

Typography, however, has many compensating advantages. Impressions are taken with much greater facility. The inking appliance glides over the relief lines to be printed from, whereas it would cling to the entire surface of the stone or the metal; hence much greater pressure would be required in these cases. The unprintable part of the stone in lithography has to be damped, so as to repel the ink; the same portion has to be inked and then cleaned off in copperplate printing; but in letterpress printing the ink only that has to be transferred to the paper needs to be applied to the type. When the design has been drawn on the stone or scratched into the copper, the result does not admit of any further application beyond that at first contemplated. But in letterpress printing the surface may be of a composite character. It may be formed of single pieces representing the several letters, and these, when once formed, may be employed in endless combinations. Only by such means are cheap newspapers and books possible. Before the invention of typography (as in the East to the present day), the dif-

ferent pages of a book were printed from wooden blocks, cut after the manner of a wood-engraving. Blocks of this kind are of no use for printing after their first purpose has been fulfilled. They must necessarily be made very slowly and with much labour. In forming a page of a book, on the other hand, by the typographic method there need (excluding necessary wear and tear) only be the cost of "composing" the types and of "distributing" them into their proper receptacles, from which they may be re-taken many times to form other compositions.

Types: their Material Characteristics.

Exclusive of such printing surfaces as wood-blocks and casts, the Book-letters, marks, and signs with which letterpress printing is executed work are called *types*, a proportioned quantity of each of the letters of fount. the alphabet in any one body or face forming a *fount*. A book-work fount contains single letters, diphthongs, ligatures (such as ff, fl), accented letters, figures, fractions, points, reference marks, dashes or metal rules (as —), leaders (as), braces ({}), and signs (as &, £). It also includes quadrats, —pieces of metal of various widths, which do not print, but are used to compensate for the shortness of occasional lines, as at the close of a paragraph—and spaces, which separate words and letters. There are thus about 226 separate characters in every ordinary English book-work fount. The table used by type-founders to regulate the number of each Bill of of the several sorts in a fount is called a *bill of type*. The sorts are type, supplied by English type-founders in certain definite proportions, depending upon the number of lower-case m's. A bill of 3000 m's usually contains the following:—

Lower-case.	Figures, &c.	Capitals.	Small Caps.
m ... 3,000	, ... 4,500	A ... 700	A ... 450
a ... 9,000	; ... 800	B ... 450	B ... 270
b ... 2,000	: ... 600	C ... 500	C ... 350

Large quads, one-tenth of fount. Italic, one-tenth of Roman.

Such a fount would weigh about 750 lb if of pica size, 480 lb if long primer, 400 lb if bourgeois, 330 lb brevier, 280 lb minion, 220 lb nonpareil. The numbers of the respective letters are based on the requirements of the English language; other languages of course require different proportions. In Latin and French, for instance, q and u would be deficient, h in excess, and w needless. The number of the respective letters may be, and sometimes is, apporportioned by weight; for example, in one of the "schemes" of founts

¹ There is a tradition in one of the oldest English foundries that this scale originated in a laborious calculation of the comparative number of different letters used in setting up a lengthy debate in the House of Commons, it being supposed then that the purest English was spoken there. The scale is, however, frequently found defective in practice. It is a curious fact, for instance, that the matter of Charles Dickens's works will empty the vowel boxes long before those of the consonants, and that Lord Macaulay's statelier style will run with like persistency on consonants.

used by type-founders a fount of 125 lb Roman with, as its complement, 10 lb Italic, includes 8 oz. of E, M, C; 9 oz. of T; 8 lb of e; 5 lb each of a, h, n, o, t; and so on, down to 3 oz. of z. To estimate the quantity of type required for a page, the number of square inches it contains is measured and divided by 4, the quotient being the approximate weight of the matter in pounds. In small founts, however, 50 per cent. is added, and in large ones 30 to 40 per cent., to allow for the letters generally left in the cases, not being required in the job, and for sorts, &c. These figures, although useful, are only approximative, the proportion of the several ingredients of type-metal used by different founders for the various sizes of type greatly varying the calculation.

Parts of
a type.

Each of the parts of a type has a technical name. In the annexed diagram (fig. 1) of the capital letter M the darkest space *a, a, a*, is called the *face*; and only that part of the type touches the paper in printing. The face is divided into the *stem*, marked 1, which comprises the whole outline of the type M; the *serifs*, or the horizontal lines marked 2, which complete the outline of the letter; the *beard*, consisting of the bevel or sloping part marked *b, b*, and the *shoulder* or flat portion below *b*. The shank is the entire body of the letter, *d*, the front part (that shown) being known as the *belly* and the corresponding part behind as the *back*. The spaces at *h* and *h* are the *counters*, which regulate the distances apart of the stems in a line of type. The hollow groove extending across the shank at *e*, is the *nick*, which enables the workman to recognize the direction of the type and to distinguish different founts of the same body. The absence of this simple expedient would retard the operation of composing types by fully one-half. The earliest type-founders did not know the use of the nick. In some letters, such as *j* and *f*, a part of the face overhangs the shank; this is called the *kern*. The groove *g* divides the bottom of the type into two parts called the *feet*. An impression from that part of a type on which it stands would be as . Types must be perfectly rectangular, the minutest deviation rendering them useless. Any roughness at the sides is called *burr*, and any injury to their faces a *batter*. Smoothness, sharpness of angle, and perfection of finish are also prime requirements. A line of types, when viewed along the back, presents the appearance of a solid bar of metal.

FIG. 1.—Finished type.

Species
of letter.

Types which have the face cast in the middle of the shank, as *a, c, e, m*, &c., and thus leave an open space above them corresponding to that below, caused by the beard, are known as *short letters*. Those whose stem extends to the top of the shank, as *b, d, f*, &c., are called *ascending letters*. Those that have a stem extending over the shoulder, as *g, p*, &c., are called *descending letters*. Those that are both ascending and descending, and extend over the whole of the shank, as *Q* and *j*, are *long letters*. Small letters and figures cast upon the upper part of the shank, as *l*, are called *superiors*; those very low down on the shank are *inferiors*, as *H*. Types that are very heavy and massive in appearance are called *fat-faced*; those that are fine and delicate, *lean-faced*. A type whose face is not in proportion to the depth of the shank (e.g., a small pica cast on a pica body) is a *bastard type*.

Specimens of
principal
bodies.

Types are of various sizes, ranging from those used in printing pocket Bibles to those for large placards. The variation is confined to the superficial dimensions of their ends, or *bodies*, as they are called. Each body has a distinctive name. The following are specimens of the principal bodies of ordinary types, and show the relation of the various bodies one to another—

Printing has been

Canon—17½ lines to the foot.

Printing has been

Double great primer—25½ lines to the foot.

Printing has been

Double English—32 lines to the foot.

Printing has been defined to

Double Pica—41½ lines to the foot.

Printing has been defined to be

Great primer—51½ lines to the foot.

Printing has been defined to be the ac

English—64 lines to the foot.

Printing has been defined to be the act, art, or

Pica—71½ lines to the foot.

Pearl—178 lines to the foot.

Printing has been defined to be the act, art, or practice of impressing letters, characters, or figures on paper, cloth,

Diamond—207 lines to the foot.

Printing has been defined to be the act, art, or practice of impressing letters, characters, or figures on paper, cloth, or othe

Gem—222 lines to the foot.

Printing has been defined to be the act, art, or practice of impressing letters, characters, or figures on paper, cloth, or othe

Brilliant—239 lines to the foot.

It is a confusing and inconvenient anomaly that the types made Size of by different English founders vary in size, although they bear the types. same name. The above figures refer to the types of Messrs Miller and Richard, the royal type-founders for Scotland; but other eminent makers supply, for instance, long primer which is 89½, 90, or 92 lines to the foot. This has been remedied in America by an agreement on the part of the founders to adopt one standard pica, to divide that pica into a certain number of equal parts, and to cast all their types as multiples of one of these parts. They divide the pica into twelve points, and the point is the unit upon which the system is based. There is also another practical advantage in this multiple system: each type bears a simple proportion to the others, and therefore can be used in exact combination. Thus pearl is 5, nonpareil 6, minion 7, brevier 8, bourgeois 9, long primer 10, small pica 11, and pica 12 points. In Germany, France, and other countries of the Continent a uniform system of points has been adopted, based on a scale of 133 "Ciceros" (corpus 12) to 60 centimetres. The types which most nearly correspond to those already mentioned are:—

	Point Ems to Foot.	Size in Centi- metre.		Point Ems to Foot.	Size in Centi- metre.
Perl 5	162.15	1879	Borgis 9	90.08	2388
Nonpareille 6	135.12	2256	Garmond 10	81.07	2759
Colonel 7	115.88	2682	Cicero 12	67.56	4511
Petit 8	101.84	2608			

The number of lines given to the foot in the above specimens of bodies is the theoretic and practically the only approximative standard. The height of types varies slightly with different founders, the mean being 3½ in. The old Scotch height is about 3⅞ in. higher. Types lower than the ordinary dimension are said to be *low to paper*, and if surrounded by higher types will not give a perfect impression. Spaces and quadrats were formerly only three-fourths of an inch in height; but, since electrotyping has become so common, they are almost invariably cut high, i.e., up to the shoulder of the type. Six lines of pica and twelve lines of nonpareil each cover an inch in depth. It is, however, not possible to know the size of a type in a printed page by placing a rule measure upon it, as many books are not set solid: the lines are not close together, but leaded out with pieces of lead, to make them cover a larger space. A communication of great importance contributed to a newspaper may be set up in the same type as the leading article; but if not leaded it will appear to the non-technical reader to be in a smaller character.

The width of pages or columns, in the technical language of the printing office, is expressed according to the number of "ems,"—

that is, of a pica m,—the square of the depth of pica. As the latter is one-sixth of an inch, the em is the same width, and a page of twenty-four ems wide is equal to one 4 inches wide. The columns of this *Encyclopædia* are 19 ems wide.

Varieties of face. According to the purpose for which they are used, types are divided into two classes—book type, including Roman and Italic, and job type, including a multitude of fanciful forms of letters, chiefly founded on the shape of the Roman and Italic letters, and intended to be more prominent, delicate, elegant, &c. It is impossible to enumerate all the varieties of the latter class, as additions are being constantly made and once popular styles always going out of fashion. The leading varieties are the antiques, which are Roman letters with strokes of nearly uniform thickness, as **M**; sanserifs or grotesques, which have no serifs, as **M**; blacks, as **M**; and scripts, which represent the modern cursive or Italian handwriting, as *M*. Black letter is now only a jobbing type in English-speaking countries, although, as stated in the historical section of this article, it was the first character used in printing. It is still used in Germany, with certain modifications, as the principal text-letter for books and newspapers. A comparison of the numerous reproductions that have been issued of Caxton's works with any modern line of black letter will show how greatly the form and style have been altered within a period of four centuries. The present style of Roman type dates only from about the first quarter of the 18th century. Previously the approved shape was as follows:—

Printing has been defined to be the act, art, or

The use of this type was revived by Whittingham of the Chiswick Press about 1843, and it has since become a favourite form, under the name of old style. Some of the punches cut by the first notable English type-founder, William Caslon (1692-1766), have been preserved and types are being constantly cast from them. Nearly all foundries now produce modernized old style. For the recent revival of old style printing, see p. 710 below.

Large letters, such as are employed for large bills and posters, are made of wood, chiefly rock maple, sycamore, pine, and lime. These are cut up, planed to the required size, and then engraved, generally by special machinery, this being a business quite distinct from that of letter-founding. The larger letters are designated as two line, three line, four line, &c.,—meaning twice, thrice, or four times the depth of face of pica or great primer, &c.

Type metal. Type metal is an alloy, of which lead is the principal ingredient; but, owing to its softness, antimony and tin are added (see vol. ii. p. 129 and vol. xiv. p. 378). A patent type metal (Besley's) was invented in 1855 in which the mixture consisted of lead, regulus of antimony, tin, nickel, copper, and bismuth. Nearly all type is now made with some of these metals superadded. Ductility, hardness, and toughness are the prime requisites of a type metal.

Making of types. The earliest printers made their own types, and the books printed from them can now be distinguished with almost as much certainty as handwriting can be identified. The modern printer has recourse to the type-founder. The first step in the making of type is cutting the letter on the end of a piece of fine steel, forming the punch (see fig. 2), which is afterwards hardened. This is an operation requiring great care and nicety (there being comparatively few adepts at it), in order that the various sorts in a fount may be exactly uniform in width, height, and general proportions to each other. A separate punch is required for each character in every fount of type, and the making of them is the most expensive branch of type-founding. During the process of its manufacture the punch is frequently tested or measured by delicate gauges to insure its accuracy. When finished it is held over a light, the flame of which blackens the letter, and thus enables an impression, called a *smoke proof*, to be stamped on paper. When the letter is perfect, it is driven into a piece of polished copper, called the *drive* or *strike* (fig. 3). This passes to the justifier, who makes the width and depth of the faces uniform throughout the fount. They must then be made to line exactly with each other. When completed, the strike becomes the matrix (fig. 4), wherein the face of the type is made. This method of making a matrix has until now been in almost universal use in Great Britain. It is, however, a very slow and costly process. In America the great majority of matrices are made otherwise. If the design of the fount to be produced is original, it is often cut by hand or by an engraving-machine on the piece of metal which is to form the matrix. If, on the other hand, an existing fount has to be copied, the matrix is made by electro-deposition.

FIG. 2.—Punch. FIG. 3.—Drive. FIG. 4.—Matrix.

A perfectly good type is selected, and inserted in a mould specially made, called a *fusible mould* (fig. 5). Sufficient metal of a more fusible nature than the type is cast round it, and forms a shape similar to that of the ordinary matrix. This fusible cast is then placed in a box protected by glass and gutta-percha, in order that the copper deposit may be kept square and to the proper dimensions. This arrangement also limits the deposition to the face. The box is immersed in the copper electrotyping solution, in which it may be left until the deposit of metal has increased to a thickness at which it may be backed up with copper, or it is left until it reaches the full thickness, which is about $\frac{1}{16}$ of an inch. It is then fitted in line, set, position, and height. The minutest imperfection or blemish is reproduced by the deposition, and the type cast from such a matrix is a perfect counterpart of the original. A school of type-engravers has recently sprung up in the United States, cutting exclusively on metal and producing ornamentation and finish which the punch-cutters cannot rival. It is expected that in the course of time the electrotype matrix will nearly supersede that made in the old-fashioned way with the punch. In the ordinary method the mould in which the body of the type is formed is made of hardened steel in two parts; one part is fastened to the machine and is stationary, while the other is movable so that it may be adjusted for the proper width of the letters, as one is wider than another. The combined matrix and mould are then adjusted to the type-casting machine, which manufactures types at the rate of from 25 to about 120 per minute, according to the body. The metal is kept fluid by a little furnace underneath and is injected into the mould by a pump, the spout of which is in front of the metal pot. The mould is movable, and at every revolution of the wheel it comes up to the spout, receives a charge of metal, and flies back with a fully formed type in its bosom; when the upper half of the mould is lifted, a type is ejected. The spring in front holds the copper matrix in close proximity to the mould. The letter a, for instance, stamped in the matrix is directly opposite the aperture in the mould which meets the spout of the pump. When a due proportion of a's are cast, another matrix with b stamped on it takes its place, and so on throughout the whole fount. The types, however, are not finished when they leave the machine. There will be found attached to each a wedge-shaped *jet* (fig. 6), somewhat similar to that on a bullet cast in a hand-mould. These are picked off by boys at the rate of from 2000 to 6000 per hour. A burr which still adheres to the shoulder of the type is taken off by the rubbers, who rub the sides on circular stones or on files. The types afterwards go to the setters, who arrange them in long lines ready for the dresser, and he slips them into a long stick, turns them on their face, and, after duly fastening them, cuts with a plane a groove in the bottom, which forms the feet. (These processes are now frequently performed by a machine, which produces types that do not require rubbing or dressing.) The types are then dressed and the picker takes them in hand, in order to pick out each defective letter with the aid of a magnifying glass. They are finally made up into parcels of a convenient size, called *type-founders' pages*, weighing about 8 lb each.

FIG. 5.—Mould.

FIG. 6.—Type with jet.

Subjoined is a description of a machine for performing automatically the various operations of casting and finishing type which was invented about twenty years ago by Messrs J. R. Johnson and J. S. Atkinson. In this apparatus the metal is fused, injected into the mould, the cast letter turned out, rubbed or planed, first on one side and then on the other, the feet cut out and smoothed, the dressed sides planed alternately, and the finished letter set up on a stick ready for use by the printer. The casting machine and the dressing machine are in reality distinct, though mounted on a common frame. The whole is driven by a steam-engine or other prime mover. The casting machine consists of a furnace covered by a shallow pot holding the fused metal. In this is a pump, and the mould is placed opposite its nozzle. The mould being adjusted and the matrix in its place, the molten metal is injected and then solidifies, forming a perfect type, but with jet attached. This letter is then thrust out, and the mould closes again for another jet of molten metal. All this is effected by one revolution of the axle of the machine. The letters pass through a channel one by one into the dressing machine. On arriving there they have each of their sides planed in succession by being held against cutters. When one side is made true with respect to the set of the letter on

its face, it is passed over a second cutter, which planes the second side absolutely parallel to the first. After this the type is carried in a line at right angles to its former course past a series of similar cutters, which plane out the foot, further smooth its surface, and plane each of the two dressed sides in succession; this completes the dressing or finishing of the types, which, continuing on their course, pass upon a composing stick and are ready for the printer. The line of types presents the appearance of a solid bar of metal, so true, flat, and square are the surfaces of the several separate letters. This machine has been considerably improved by Mr P. M. Shanks. The new machine is of simpler construction and its parts are more compact. It does not produce better type, nor work quicker,—the speed in all type machines being regulated by the time required to cool the volume of metal, which, when on the machine, is assisted by having water percolating through the heated parts of the mould. The working of the new machine is more readily grasped by the manipulator, and there is considerable reduction in its cost.

Type-Setting or Composing.

We may now describe the manipulation of the types in the printing office, and for the sake of conciseness reference must be made only to the operations connected with ordinary book-work. These differ in details from the methods in use in the other two departments of the printing business,—news-work and job-work.

Type-case.

The types, received from the foundry in the packages called pages, are placed in shallow trays called cases. These contain compartments or boxes, each of which is appropriated to some particular sort or character. The cases when in use stand on frames or sloping desks. The case at the top is the *upper case*, and that below the *lower case*. The former contains ninety-eight equal-sized boxes, appropriated principally to the capital and small capital letters; the latter has fifty-three boxes of various sizes, appropriated

FIG. 7.—Type-case.

to the lower-case sorts. The difference in the size of the boxes corresponds to the difference of quantity of letters in a fount, as already stated,—the lower-case e for instance having the largest box. The localization of the letters, &c., is a subject on which opinions differ, the object being to bring the letters most frequently required nearest to the hand of the compositor as he stands at work. As a man picks out from the boxes seldom less than 1500 letters per hour and distributes or replaces on the average about 5000 per hour, it is necessary that the most economical allocation of the boxes should be adopted. The system of allocating the various types is called the *lay* of the case; fig. 7 illustrates the plan used in the principal English book offices; but there are many deviations.

Composing.

The types when taken from the cases are arranged in lines or "composed" in an instrument called a *composing stick*, made of iron, brass, or gun metal. The slide in the middle is movable so as to accommodate varying lengths of lines. In the composing room the frames are arranged in rows, supporting the cases. The compositor fixes the "copy," or document which he is to repeat in type, in a convenient place before his eye, and on some part of the case that is seldom used. In his left hand he holds the composing stick, and with the thumb and first finger of the right hand lifts the letters from the boxes, and arranges them in the composing stick, every letter, point, or sign being picked out separately. In this operation he is much assisted by the use of a *setting-rule*, a thin brass or steel plate which, being removed as successive lines are completed, keeps the type in place. When so many words and parts of words as will nearly fill the line have been composed, it is made the exact length required by inserting or diminishing the space between the several words. This is called *justifying* the line and is effected by means of the spaces already mentioned. If the work is not "solid"—that is, if the lines are not close together—the strips of metal called *leads* are used. They vary in thickness, but always form aliquot parts of pica body. A good compositor must possess intelligence and a reasonable amount of general knowledge: he must be able to read his copy with readiness, and to understand its meaning, in order to punctuate it properly. He should be able to spell correctly, as some copy is almost undecipherable in regard to separate letters, while other copy is incorrectly spelt. When the composing stick is filled, the type is lifted on to a *galley*, a shallow tray of wood or metal, two or three sides of which are flanged, for the purpose of supporting the type, when the

galley is slightly inclined. Stickful after stickful of type is placed on the galley until it is full. The matter is then fastened up, a proof taken at the proof press, and the work of the reader or corrector of the press—described below—begins. The proof, marked with the necessary corrections, is given back to the compositor, in order that he may make the required alterations in the type.

The type, being duly corrected, is made up into pages of the *Impos-* required length (unless the author has desired to see proof in *ing-* *skip*). It is then *imposed*, that is, the pages are arranged in such a manner that, when printed and the sheet folded, they will fall in due numerical sequence. The impression from any arrangement of pages will be the reverse of that in which they are laid down. If an ordinary four-page newspaper supplement be opened and spread out with the first page uppermost, it will be found that on this side the order of pages is 4, 1; when turned the pages are 2, 3. The type pages must be ranged in the reverse way, as 1, 4; 3, 2. Thus the fourth page is placed alongside the first, because both must be printed together on the outside; the third page is to the left, and the second to the right, because in books the odd page—the *verso*—is always to the right. For a quarto a sheet of paper is folded twice, that is once across its breadth and then once in a perpendicular direction down the middle. It contains four leaves, and if these are printed on both sides eight pages. The two sides of a sheet are called the outer and inner formes respectively. A sheet of octavo is folded three times, making 8 leaves or 16 pages. The size of a book depends, not only upon the number of times the sheet has been folded, and described accordingly as 4to, 8vo, 12mo, &c., but upon the size of the sheets. The dimensions of the papers commonly used in book-printing are:—imperial, 22 × 30 inches; super royal, 20½ × 27½; royal, 20 × 25; medium, 19 × 24; demy, 17½ × 22½; double crown, 20 × 30; double foolscap, 17 × 27; post, 15½ × 19½. Hence to say that a book is a quarto merely gives no precise indication of its dimensions, as a quarto of one size of paper may be smaller than an octavo of another; it is also necessary to know the size of the sheets of which it is composed.

When a printed book is opened, it will be found that at the foot *Signa-* of certain pages there is usually a letter and at the foot of another *tures.* a letter and a figure, as B, B 2; further on another letter and another letter and figure. On going through the book it will be seen that the letters are in regular alphabetical order, and occur at regular intervals of eight, twelve, sixteen, &c., pages. These designate the several sheets of which the book is composed and are called *signatures*, so that a sheet may be designated B, and the pages of which it consists are thereby sufficiently indicated. (Occasionally, as in the present work, numbers are used instead of letters.) These signatures assist the binder in folding, as they occupy a certain specified place in each sheet; hence to ascertain if the sheet has been folded properly it is only necessary to examine the position of the signature. The binder also is thus assisted in *gathering* or collating together the sheets of a volume in proper order. Signature A is omitted, because it would be on the title or first page, and would be both unnecessary and unsightly. By old custom J, V, and W are discarded, I and J, U and V being originally used indiscriminately by printers, while W was written UU or VV. When the alphabet is exhausted, a new one is commenced, distinguished by a figure precedent, as 2 B, 2 C, &c.

The pages of types are arranged in proper order on a flat table, *Forme.* covered with stone or metal, called the *imposing stone*, and are then ready to be made into a *forme*, that is, in such a state that they can be securely fastened up and moved about. The forme is enclosed in an iron frame or *chase*, subdivided by a cross bar. The portions of the type are separated by *furniture*, which may be of metal or wood or both. It is of the same height as the chase, but lower than the type, and therefore does not print, but forms the margin of the printed pages. At the sides of the two sections of the formes are pieces of furniture of a tapering shape, called *side-sticks*, and at the top and bottom corresponding pieces, called *foot-sticks*. Small wedges, called *quoins*, are inserted and driven forward by a mallet and a *shooting-stick*, so that they gradually exert increasing pressure upon the type. Other mechanical means for locking up are also occasionally adopted. When sufficiently locked up, the whole is quite as firm and portable, however many thousands of pieces of metal it may consist of, as if it were a single plate. In this rapid sketch we purposely omit mention of several operations which, though important and indispensable, are only of interest to the workman.

For many years endeavours have been made to construct *Type-* machines for type-setting which should obviate hand labour. *setting* Picking out the types separately from their boxes and arranging *machines.* them singly in the composing stick is an irksome and monotonous operation, and one which it might be thought comparatively easy to perform by automatic machinery. But of the many different composing machines that have been invented less than half a dozen have stood the test of practical experience. These have been confined to special classes of work, and it is open to doubt whether the nimble fingers of a good compositor, aided by the brains which no machinery can supply, do not favourably compare on the

ground of economy with any possible mechanical arrangement. On the other hand, employers and makers of machines allege that owing to the opposition of the men machine type-setting has not had fair play. However that may be, it is undeniable that a composing machine is still rare in printing offices, and where employed it is only as an auxiliary to the ordinary labour of the men. It deserves to be mentioned that nearly the whole of the London *Times*, with the exception of the advertisements, has for years past been set up by machinery, and that more than 10,000 pages of the present edition of the *Encyclopædia Britannica* have also been so set up. We have not space to describe with any minuteness the construction of composing machines. In the Fraser machine (fig. 8), one of the simplest of its class, which has been made use of to the extent already mentioned in the present work, the types are contained in a series of grooved trays A, in the upper part of the machine, the trays having previously been filled by complementary apparatus called the *distributor*. In these trays the types are kept in position, and pressed towards the front part of each tray, by slips of metal attached by cords to the box-wheels B; each of these contains a spring of sufficient strength to press the line of

FIG. 8.—Fraser composing machine.

types steadily forward against the separators C, which are formed with an inverted shoulder, under which the front type in each line passes. The keys are connected by levers to the separators, and the depression of any key causes the corresponding separator to descend, carrying with it the front type of the line into the grooved face-plate, down which it slides into the composing stick G. Immediately the finger is lifted from the key the spiral spring D raises the separator to its original position, and the next type in the line takes the place of the one just released, and so in succession as fast as the keys can be pressed. Under the keys runs a rod connected by a crank motion with the pusher G, which, with every depression of a key, pushes forward the line of type in the composing stick, thus making room for the next letter. The matter is thus set in one continuous line, ready to be divided into lines of the required length either by the operator at the machine or by another hand working in conjunction. The speed of the machine varies from 6000 to 12,000 types per hour, but is regulated solely by the skill of the operator, as the machine will work as fast as the keys can be pressed. The composing machines now employed at the *Times* office are an improved form of an apparatus invented by Charles Kastenbein, and introduced there in 1872. The operator sits in front of four rows of keys one above the other, something like the manuals of an organ, but only about 3 feet wide. Each of the keys corresponds to a type or character. The types are kept in tin tubes placed vertically at the top of the machine. The depression of a key works a series of levers, and an iron finger pushes the undermost type from its tube, when it falls into a groove formed in a conducting plate, narrowing at the bottom to its apex. Immediately below is a receptacle, and by the action of a treadle the type is pushed along a channel. Other letters follow, the matter being thus set up in a long line, on a groove of the width of an em quad, and running from left to right. The type when it first comes into the groove is in an upright position, but in passing along it becomes twisted, so that the letters stand at an angle of about 45° when they reach the point at which they are justified. This groove communicates at its dexter extremity with the justifying galley,—a simple apparatus, something of the nature of a composing stick and galley combined. Then the type is divided into portions or lines of the required length and justified in the galley, which is adjustable to the width of the required length. As the long line approaches him, the justifier with a small bodkin accelerates a portion large enough in his judgment to fill the width of his column. When this is done he presses his foot on the treadle under him, and thereby causes the line to be pushed into the galley. The line is justified by spaces and quads, and enough type is then taken for another line. The speed depends on the operator, and varies from 6000 to 13,000 types per hour, the average being about 8000, with two operators,—a justifier and a compositor being also necessary. These machines are worked in the *Times* office at the rate of a column of solid minion an hour. The machine occupies a floor space of only about 4 feet wide by 2 deep.

Another machine at present in use is that of Mr Robert Hattersley of Manchester. It probably furnished the general scheme of others in use. One of the most ingenious machines of the kind is that of Mr Alexander Mackie of Warrington, its general principle being

the adoption to setting up types of the Jacquard card of the power loom, which weaves automatically the most intricate patterns of cloth. The apparatus consists of three parts,—two used for preparing the “card” or ribbon, which directs the third in the operation of type composing. The perforator is like a small cottage pianoforte. When the keys are struck they produce a perforation, and the ribbon is made to move aside a little, so that a new surface may be presented for puncturing. The composer is a circular iron table, 4 feet in diameter, having round its periphery a number of boxes divided into sections, each of which holds one kind of type. On a slightly lower plane is a wheel carrying little brass tables, hinged at one end. When the machine is in motion, the types are pushed out on to the table, which passes with its freight round its course until it comes to the point of delivery, when the types are swept off. The rising of the table, and the drawing out of the types, are guided by the perforated paper. Hence the machine sets types without a human compositor. When once the ribbon is perforated, it may be used over again for subsequent editions of the same work, which may be in a different size of type. These machines are only in use in the office of the inventor.

As has been already described under REPORTING (vol. x. p. 406), the parliamentary reports of some newspapers are set up entirely without copy,—by the ear, not by the eye. It has been found that by the aid of the machine the matter can be set up half as fast again as it could be written out: the average speed of the composing machine is 230 lines per hour when the copy is dictated to the operator, whereas the most skilful workman setting at ease in the usual way can do but 50 lines per hour.

For many years it was a favourite idea with inventors, especially Logotyper those who were not practical printers, that great economy might be types gained in composition by the use of word-characters or “logotypes,” instead of single letters. The constant repetition of many words seemed to suggest that they might be cast in one piece. Combinations suitable for affixes and suffixes, as ad-, ac-, in-, -ing, -ment, &c., it was also suggested, should be used instead of the single component letters. The suggestion has, however, not been carried out, at least to any considerable extent. The chief practical objection to it is that it involves the use of cases with an inconveniently large number of boxes. The more the variety of characters is multiplied the more “travel” of the compositor’s hand over the cases is necessary for picking them up, and by so much is the speed of his work retarded. Logotypes, too, are more liable to accident; when one letter is damaged the combination is rendered useless.

The correction of the type is a subject that should be understood Correct- by all who have to do with printing, as many mistakes are made ing type. on the part of authors which a little technical knowledge would prevent. In the course of setting any copy or MS. which may be given him the compositor unavoidably picks up some wrong letters, or mistakes the words in the copy before him, or fails to follow the style prescribed for the work. These are called *printer’s errors*. When the compositor has finished his task, a *first proof* of the matter is taken. This proof is read through and compared with the copy by the proof reader or *corrector of the press* and an assistant, the *copy-holder* or reading boy. The proof is then sent back to the compositor and the latter is required to correct all the inaccuracies indicated therein—in fact, to attend to all the directions given by the reader—and this has to be done at his own cost if he is working on piece—that is, paid by results according to work done—or by the employer if he is working “on establishment wages” or paid by time. Another proof called a *revise* is now taken; this is carefully compared with the previous proof. If the corrections have not all been made, the revise is marked accordingly, and sent back to the compositor, who is required to remedy the imperfections. When the proof is deemed accurate, or “clean,” it is sent, generally along with the copy, to the author,—being now termed an author’s proof. Finally, in the printing office the matter is carefully re-read and compared with the last author’s proof by the press reader, who signs it and on his responsibility the type is printed off.

The operation of distributing the types is the converse of that Distrib- of composing: it is de-composing the forme and returning the buting several letters to their proper boxes in the case. It is done, as already type. mentioned, with remarkable rapidity. The forme is first washed over with an alkaline or other detergent to remove the ink from its surface, and then laid down on the imposing surface, unlocked, and damped; this assists the cohesion of the type, after the chase, furniture, side sticks, &c., are removed. The compositor then takes in his left hand, supported by a setting rule, a portion of type in lines, and with the right hand takes a word or so between the finger and thumb, letting each letter drop separately into its proper box. There is hardly any operation which so strikes a spectator as distributing, for a competent distributor literally showers the types into their receptacles. The types are held upside down, that is, with the nicks uppermost; hence the letters of each word are read from left to right like ordinary matter when printed, but the words are of course dealt with in the inverse order.

Distributing machines of many different kinds have been invented.

Type-distributing machines. They may be divided into two classes,—those worked entirely by keys or notes, like the pianoforte, and those in which the distributing is to a certain extent done automatically. For the former class only the type in ordinary use in printing offices is required. For the latter the type requires to be specially prepared, each character having a distinctive nick or nicks upon it, which correspond with the particular channel of the machine it is intended to occupy, and by which it is guided to its special compartment. Kastenbein has produced a distributor which may be described as a composing machine reversed. The matter to be decomposed is placed at the top in its appropriate tray or fixed galley, the sides of which are adjustable to fit any measure, the back being so constructed that it may be advanced to keep the matter always up to the front. As the matter is pressed towards the front, the first letter of it is brought in contact with a steel pusher, behind it being an aperture communicating with the channel of the guide plate. The matter is read by the operator; and he touches the key corresponding to the letter that comes first. Thus the types are conveyed one by one to the guide plate or conductor. It has grooves furnished with little gates or switches, like the points of a railway, and these direct the types into their proper channels. The tubes into which the types are deposited are placed at the foot of each groove. Thus every time a key is depressed the switches move, the pusher sends the type to be distributed out of the line, it falls through the aperture, and, passing down the channels in the guide plate, reaches the proper tube. The speed is to a certain extent dependent upon the skill of the operator, but averages between 3500 and 4000 per hour. A good compositor can by hand alone distribute as many letters as this. But for the purposes of the composing machine, hand distributed types would have to be set up again, as the composing machine is supplied not from ordinary cases but from tubes of type. In the Fraser distributing machine (fig. 9) the page of matter to be distributed is placed on the upper part of the machine at H, whence by suitable apparatus it is moved line by line towards the separator I in front. The matter is there read by the operator, and as each letter comes in contact with the separator the corresponding key is pressed and the type is conveyed to the guide plate, where a series of switches guide it to its proper compartment in the tray of the composing machine.

FIG. 9.—Fraser distributing machine.

Stereotyping, Electrotyping, &c.

The method of reproducing and multiplying letter-press printing surfaces by taking casts of them, or stereotypes, has greatly conduced to the progress of typography,—much more so, indeed, than might be realized by those who are unacquainted with the practical details of the art. Stereotyping (*στερεός*, fixed or solid; *τύπος*, type or forme) is the method of taking casts from a fixed or movable forme; thus, printing from stereotypes is distinguished from typography, in which impressions are taken from movable types. It does not supersede type-founding, but supplements it, for a page of reading matter requires first of all to be set up letter by letter, and then the casts or plates are taken, each of which may be printed from with nearly as much perfection as from the original forme. Hence a printing surface may be reproduced to an almost infinite extent, and the means of production of impressions on the press or machine are increased in proportion to the number of casts taken. It ensures an accurate copy of an original text, whereas in reproduction by resetting the movable types there is a liability to deviation. When only a cast is worked from, any accident may be repaired by taking another cast, and the cost is slight compared with that of composing over again. A smaller quantity of type may be used in an office where this process is used; a portion of a work may be set up, a cast taken, and the types returned to the cases. The plates are more easily stored than movable formes, and are not liable to the danger, as in the latter, of types falling out. Above all, the mould may be bent to any curve required, and a circular cast obtained, which may be fastened round the cylinder of a machine (see *infra* in regard to rotary printing).

The process of stereotyping, divested of merely technical details, is as follows. From a forme of matter, which may be wholly or in part composed of movable types, a matrix or mould is taken. The original is in rilievo; the mould consequently is in intaglio. From this the stereo plate is cast, and it of course is again in rilievo. This in turn may likewise become an original, and casts may be taken from a plate, or other casts from the same mould. The first books were printed from solid wooden blocks, each of which formed a page. Then came the era of typography, in which these pages

were composed, mosaic-like, of movable types. Now has succeeded the period of stereotyping, in which pages formed of single blocks—but of metal, not of wood—are used. The two essential parts are, therefore, the making of the matrix and of the cast, which is composed of an alloy something like that for type metal. The mould may be of plaster of Paris or papier-mâché; the latter being the simplest material, and that almost universally used, need alone be here referred to. The following account of the process, when carried out on the smallest possible scale, is sufficient perhaps to show the general principles of the art. The papier-mâché for the mould, called *fiong*, is made by uniting several sheets of paper with a paste made of wheaten flour, starch, and alum, to which whiting is added. These ingredients are often varied; the general object in using them is to obtain a paste which will stand a high temperature without burning. A sheet of brown paper is laid down on a smooth surface and pasted over; blotting paper is laid on that and pressed down, then pasted over, and a sheet of tissue paper added, which is also pasted, and another sheet of tissue paper placed on the top. This is well smoothed and pressed to give the incorporated material greater firmness and cohesion. Next, to prepare the forme for being moulded, it is surrounded with metal “clumps” of the height of the type, placed close to the matter, and then oiled to prevent the fiong sticking to it. The latter is then thoroughly damped, to render it quite plastic. The forme being on a level surface, the fiong is laid upon it, and on that a piece of linen. The surface is next well beaten all over with a long-handled brush, till the fiong sinks into all the declivities of the forme and receives a deep impression of it. This is a process requiring experience and practice. The linen being removed, a piece of very stout paper is laid on the top, and also beaten down, so as to strengthen the fiong, and the moulding is finished. The next point is to dry the mould.

In the most rudimentary method a combined drying and casting press is used. It consists of a flat iron surface, with a lid attached to one end by hinges. Over the surface is a cross-head fitted with a screw; pressure may be exerted on anything placed between, the arrangement being like that of a screw letter-copying press. The cross-head can be moved to one side when it is necessary for the lid to be lifted up. Underneath the press is a series of gas jets, by means of which the bed plate is heated. The press stands on supports, but is attached to them only by an axle, and it can be readily changed from the horizontal to the vertical position. The lid of the box is raised and the forme with the fiong upon it placed on the centre of the iron surface. After being covered with a blanket, the lid is screwed down upon the whole, and, the gas being lighted, the forme and mould are heated for a few minutes, after which the lid is raised, the steam evaporates, and the fiong, which has now become the matrix, is thoroughly dry. In large stereotyping foundries, after the fiong has been well beaten upon the forme, until the impression of the types is plainly seen on the back, it is baked and dried (the forme still underneath) on a long thick iron slab, called a *hot chamber*, because it is heated from within by steam. The matrix is then removed from the forme, and any superfluous margin cut away or trimmed; after this the matrix is dusted with powdered French chalk and is ready for being cast from.¹ A method has lately come into use for obviating the necessity of keeping the matrix on the type while it is being hardened by drying by heat, whereby the type is injured. The matrix is dried separately, being removed when moist from the forme, as soon as the impression is obtained. It is then placed on a bed of sand heated by gas. The forme is never heated, and there is a great saving of time, because the drying can be done in two minutes. The matrix is laid on the bed of the casting box face upwards, with gauges around it to determine the height or thickness of the cast. The lid is put down and screwed tightly, and the position of the press altered from the horizontal to the upright. The metal is then poured in and the press restored to its former position. The matrix is carefully raised and the plate exposed. It has only to be “trimmed,” the superfluous metal cut away, and the back planed, to be ready for mounting on a block of wood to make it type high.

In stereotyping for the Walter and similar presses the process Stereo is as follows. The forme is laid on the table of the moulding typing machine and the fiong placed on it and thoroughly beaten in by a hand or passed through a moulding machine, which performs the Walter same operation. The forme is next placed on a heating surface, press; and when nearly dried the matrix is removed from it and again dried. It is then placed in the casting box, which is curved to the circumference of the cylinder of the press. The box, being on a swivel, is set upright. The metal is now poured in from a ladle and the plate cast. It is allowed to stand a minute and then taken out, still hot, and placed upon a “finishing saddle” of the same circular form as the back of the plate, and secured by clamps and screws. An angular-shaped knife or chisel, fixed in a carriage, is moved by a handle in a semicircular direction across the surface of the plate, in order to remove superfluous portions of metal and to form a bevel whereby the plate can be subsequently

¹ These matrices can be preserved for several years, and the stereotyping process postponed until actually required.

clamped on the machine. If necessary the plate may be smoothed at the back by a specially-contrived planing machine. The plate is now ready for being placed on the printing machine. Each single operation can be performed with the utmost possible despatch. If the organization is sufficiently perfect, the time for making a plate, from the moment when the forme comes down from the machine-room to that wherein the perfect plate is set on the machine, need only be about eight minutes.

In newspaper establishments where stereotyping is thus adopted the pages are not all made up simultaneously: some are kept open till the last for the latest telegrams. The moment a page is completed and locked up in its chase it is sent down to the foundry, and as many casts taken as there are printing machines to be set going. One page follows another with rapidity, the first being placed in position on the machine, while the later ones are in the foundry. When all the plates are finished and fixed in their places, six, eight, or ten machines may be simultaneously printing at the rate of nearly 12,000 per hour each. The enormous increase in the circulation of the great daily newspapers would have been impossible but for the extraordinary facilities for rapid production provided by stereotyping. This process is also of special utility to the newspaper printer in the case of telegrams arriving late. In machines which printed from the type, late telegrams could only be inserted by a "stop-press"; that is, the printing was interrupted while the alteration was being made. But, when the papier-mâché casts of the pages have been taken, the type itself is liberated and sent back to the composing room, so that, if later news arrives while the machines are running, the foreman printer alters the page, a fresh cast of it is taken, and a machine started without interrupting the production for a moment. The London evening papers have usually five editions, and for every edition fresh casts are made of one or more of the pages.

Quite recently the substance called celluloid has been introduced instead of the metal referred to previously. A mould is made of yellow oxide of lead and glycerin formed into a semi-fluid paste, which is applied to the surface of the type. The matrix is placed on a powerful press and a heated sheet of celluloid about $\frac{1}{8}$ of an inch thick is laid on it. When pressure is applied, a perfect facsimile is obtained, and it is ready to be printed from when mounted in the usual way. Whereas a good electrotype from a wood block averages six hours in its production, a cast in celluloid can be got in less than an hour. These blocks are very tough and many thousands more of impressions can be printed from them than from stereotypes without their showing signs of wear. For small stamps india-rubber is used as a stereotyping material, and afterwards vulcanized. These stamps, being flexible, print on rough surfaces which would not take an impression from ordinary stereotypes. With a flexible surface, too, much less pressure is required.

Machines have been invented to do away with the use of types altogether. The principle is to punch the characters successively on some substance which will act like the fong and become a mould from which stereo plates may be cast. In an apparatus recently introduced the fong is a prepared piece of millboard, which is placed in front of the steel punches. The latter are driven into the fong with lightning speed and great accuracy. By turning a handle all the Roman punches are changed to Italic; by another a set of sanserif or other founts comes into play. For setting time-tables and logarithms the apparatus is said to save ninety per cent. over the ordinary system of hand-setting. The obstacle to the more general use of it is the difficulty of correcting errors. In another machine the punches are driven into a block of teak wood. They are cast to thicknesses which are the multiple of a "point"; hence by a simple calculation they may be spaced out to the exact number of points chosen for the length of the line, and every line leaves the machine justified. The block when complete is removed and a stereotype taken, which can be printed as in the ordinary method of typography.

For the reproduction of wood engravings electrotyping has nearly superseded stereotyping, as it produces much better copies. For obtaining plates of type matter it is also better than stereotyping, as many thousands of impressions may be taken without reducing the sharpness of an electro, while ordinary stereotype would be almost worn out by printing a much smaller number. This arises from the superior hardness and toughness of copper, of which the surface of the electro is formed. Electrotyping, however, is costlier and slower.

The forme to be electrotyped is placed upon a level plate, and surrounded with type-high clumps or metal furniture, and then floated with plaster of Paris, which prevents the mould of wax (to be afterwards made) from penetrating too far into the interstices of the spaces. The forme is next brushed with finely powdered blacklead or plumbago. The moulding composition is made of melted wax, with the addition of a little blacklead. This is poured into a shallow metal moulding tray, to which two pieces of stout wire are soldered, in order that it may be afterwards suspended in the depositing trough. After the composition is cooled and set its surface is brushed with blacklead, and it is then ready for moulding.

The moulding press may be something like a letter-copying press, or, in a large establishment, may consist of a powerful hydraulic or other press capable of exercising a pressure of many tons. The forme is placed exactly under the centre of the platen, with the moulding tray containing the wax, slightly warm, upon it. An impression is then taken, and the mould afterwards separated from the forme. The mould has next to go through the process of *building*, that is, heated wax is dropped upon such portions as should be more deeply sunk in the finished electrotype plate, namely, the places where "whites" are to appear in the print. The mould, having been finished, has to be blacklead, plumbago being a conductor of electricity, while wax is a non-conductor. The material is well brushed in, filling all the interstices of the forme; and the entire surface of the mould must be properly covered, to ensure a perfect deposit of the copper. To facilitate this operation, a blackleading machine is used in large establishments. The forme is placed upon a carriage formed of transverse bars and is moved backwards and forwards by a handle and rounce to bring it under the blacklead brush. After the mould is blacklead, the back of the moulding pan is coated with wax, to prevent the copper from being deposited upon it. The mould is now quickly immersed in one of the compartments of the battery. The process of depositing a copper solution upon the blacklead surface of the mould is continued until a solid plate is formed, which, though it is scarcely thicker than a finger nail, being about $\frac{1}{16}$ inch, forms, when properly backed, the best and most enduring surface for letterpress printing that has been discovered.

The moulding tray containing the mould is hung on the brass rod of the depositing trough facing a plate of copper, and the connexion of the battery made: that is, the mould is attached to one pole of the battery and the plate of copper to the other. The copper, so to speak, is decomposed on the one hand and recombined on the other: in other words, the current of electricity being complete, and the mould submerged in the sulphate of copper solution, the deposition of copper on the mould at once commences. Here it remains until the deposit is sufficient, the time usually occupied being from 8 to 12 hours, according to the state of the solution and the strength of the batteries. The dynamo-electro machine, which is now employed in large houses, very materially reduces this period; otherwise Smee's batteries are generally used. When the deposit, or, as it is called, the *shell*, formed on the wax mould is of proper thickness, it is disengaged from the wax,—the mould being placed with its back on an inclined board, and boiling water poured over the shell, which melts the surface of the wax, except a thin coating, the removal of which is effected by placing the mould and shell on a steam heating table. Thus the wax mould is destroyed, and it is not possible to obtain more than one shell from a mould, whereas the stereotype process enables almost any number of casts to be taken from the same matrix. The shell, being too thin and fragile to be printed from, is next backed, or filled up with metal of a somewhat softer kind than stereo metal. The shell, after being further cleaned, is lowered on to the top of a vessel of molten type metal; and, when the solder previously used to unite the copper and the metal has fused, the latter is poured over it in a molten state until it is covered. The plate is washed, dried, and polished, the back roughly planed to a surface parallel to the front, the edges squared, and all imperfections made good. The thickness of a plate is usually a pica or $\frac{1}{16}$ th inch. It is mounted as an ordinary stereotype plate. Within the last few years the process has been greatly facilitated by the employment of specially contrived apparatus, and illustrations can be produced in three hours from the time the mould is made. Curved electros are produced, as well as curved stereotypes, for use in rotary printing. Facing with nickel by the electroplating process is now largely adopted for hardening stereotypes and electrotypes and rendering them more durable. This process also prevents the deterioration of such plates by the action of the acids or other chemical reagents often present in printing inks, such as cyanide of potassium in red ink and nitric acid in some blue inks.

Polytyping is a method invented in France about the end of the 18th century, but now seldom practised in the United Kingdom. The apparatus somewhat resembles a pile-driver. It has two upright guides about six feet high, and a pulley at the top, which elevates by means of a rope a heavy plate, on which the matrix is placed in an inverted position. At the foot of the machine there is a substantial iron bed, upon which the operator places some molten metal. He then pulls the rope until the matrix, with its weight attached, is elevated to the top of the machine, when it is suddenly allowed to fall. The result is similar to that made on a medal by means of a die,—a perfect reproduction of the matrix in relief, which is mounted on a metal stand to type height. The results are excellent, as the plastic metal is forced into the finest lines of the matrix. Duplicates of a block can be thus produced more rapidly than by the ordinary stereotype process; and another advantage is that the intaglio parts are much deeper,—a point of some importance in printing. The matrix may be made from the block by the electrotyping process.

Substitutes for Wood-Engraving.

Process blocks. Formerly the only available method of obtaining illustrations which could be printed on the letter-press in conjunction with type was that of wood-engraving. At the present time a number of comparatively new processes are in operation, in which the engraving is done almost automatically by the adoption of chemical processes and the well-known principles of photography. Engravings of this kind are called in the trade *process blocks*, or sometimes *zincotypes*, owing to the metal of which they are formed. There is space here for only the barest possible account of the processes.

Typo-etching. In the first method, which is sometimes called *typo-etching*, the drawing is made with ordinary lithographic ink on stone, or on paper and transferred to stone. It is then re-transferred to a plate of polished zinc by the ordinary lithographic process. Zinc is employed on account of its cheapness and its ready solubility in the acids used for etching. It has properties similar to those of the lithographic stone in taking up the ink and the water. The transfer is made to adhere to the plate by being passed through a lithographic press; the paper is then stripped off; and the whole of the ink is left on the plate, which is inked up as a litho stone with a view to render the lines as solid and strong as possible to resist the acid. The covering of the lines is strengthened by dusting powdered asphalt or some other suitable material over the plate, which is warmed just sufficiently to incorporate the asphalt with the ink. The plate is next placed in a bath of acid (its back and other parts, where the acid is not required to act, being protected by varnish), in order that the unprotected parts, or those which are to form the whites of the finished picture, may be dissolved away. In order to prevent the acid eating not only straight down into the plate but on the sides of the furrows it forms, and thus undermining them, an ingenious device has been adopted. As soon as the etching has proceeded to a very slight depth, the plate is removed from the bath, washed, and heated. The ink and other protective medium are thus melted and run down the sides of the little furrows formed by the acids and thereby protect them from further action. Inking and dusting with resinous material are repeated, and etching resumed, until the depressions of the block have been brought to the proper depth. The etching is carried on in troughs to which a rocking motion is given, so that the acid flows to and fro in waves over the surface, and little bubbles of gas, &c., are carried away. Where large spaces of white occur, the metal is cleared away by a drill; after the block has been mounted type high, it is ready for the printer.

Tone blocks. This process is only available for the production of "line blocks," i.e., those in which the original drawing is done in lines or dots, as for an ordinary woodcut. The highest achievement of process blocks has been the production of *tone blocks*, which may be made direct from oil-paintings, water-colours, photographs, drawings in chalk, wash, pencil, &c., or indeed from anything from which a photographic negative can be taken. The exact nature of the processes is a trade secret, but the rationale is given in Mr Truman Wood's *Modern Methods of Illustrating Books* (London, 1887), to which we are indebted for the following details. The problem is to translate, as it were, the light and shade of the negative into solid outlines of black and white. The shades must be lines of various breadths or of various distances apart, or spots or grain of various degrees of fineness or closeness. In a surface-block any part that touches the paper prints, and any part that does not touch the paper does not leave any mark at all. The photographic image is continuous: there are no outlines in it, the picture being formed of graduated tints or shades, ranging from the white of the paper up to the darkest colour that the process employed can give. To make a block for letter-press printing the graduated tints of the photograph have to be broken up into stipple or grain, and it must be a stipple closest in the shadows, gradually becoming more open through the range of the intermediate tones, and vanishing altogether in the highest lights. To describe the ingenious methods adopted to secure this end would involve an account of several photographic operations which would be out of place here. In one process, perfected by Meisenbach of Munich in 1882, grained negatives are produced by placing a transparent screen, on which a suitable grain is imprinted, in contact with the negative or the positive to be copied, and then photographing the two together. The negative is transferred to a plate of suitable material, which is grained or etched in the usual manner, to form a typographic block. Another device is to print from the original negative upon a piece of silk, the threads of which break up the picture into a regular grain. The positive on the silk is then photographed and a printing block made. These blocks require from their very low relief delicate and careful printing, but are made to give excellent results.

Typo-graphic etching. A process of typographic etching has been invented by Messrs Dawson, in which the design is drawn with an etching needle on a brass plate covered with a wax etching ground, in the same manner as for an ordinary etching. The metal is therefore bared at the lines, which are separated by ridges and spaces of wax. These spaces are

strengthened by the addition of melted wax, which runs up to the edges of the lines, but does not run over on to them as might be expected, filling them up. The supply is continued until the spaces between the lines, representing the whites of the finished print, have been raised to a height sufficient to give the necessary relief, when an electrotype is taken. This electrotype forms the printing surface.

Shanks's process is a device for producing pictures simply by the Shanks's use of mechanism, and is an application of the eidograph. The process. plate to be drawn upon is moved under the drawing implement, which is a rapidly revolving cutter, and the plate on its carrier is mounted on the end of a series of levers in the same way as the slide rest of a lathe, so as to have motion in two directions, one at right angles to the other, and consequently by a combination of the two to have motion in any direction in the same plane. If a plate of a suitable substance, such as hardened plaster of Paris, be mounted on the carrier, and the bracing point at the other end of the lever be moved over the lines of a drawing, the cutter will plough a little furrow, which will follow these lines. When the plate is finished, a stereotype is taken from it and forms the printing surface. The lines of the casts are remarkably strong owing to the conformation of the furrow of the mould, and they can be printed on fast rotary machines. The weather charts given in some newspapers are produced by this process. A block with the recurring outlines being made, plates are moulded from it, so that the details alone have to be separately cut upon future plates. Mr Shanks's method is remarkably simple and expeditious, and the results are economical and trustworthy.

Press-Work and Presses.

The characteristic of printing, as already pointed out, is that the pigment—the ink—with which the printing surface of the type is coated is transferred to the paper or other material by pressure. The manner in which this pressure is exerted gives rise to two classes of machinery,—those in which the platen and the cylinder respectively are employed. After the paper is placed on the type, in the one case a flat plate of iron moves parallel to the forme and comes in contact with it, causing the impression on the paper, while in the other case a cylinder revolves over the surface, which travels in gearing with the cylinder.

Space does not permit of any sketch, however slight, of the origin and progress of type-printing machinery. We can only refer to what may be regarded as representative appliances in present use. In America all kinds of apparatus for printing are called "presses"; in England, however, an appliance of a more automatic character than the hand-press is usually called "a machine." As the hand-press is now almost obsolete, this distinction will probably be abandoned, and the shorter and more expressive word "press" be applied to all. Venturing to adopt this suggestion, we may say that of platen presses there are the hand-press, the treadle platen press, and the steam or other power-driven press.

Fig. 10 is a view of the Albion press. It is wholly of iron and Hand-steel. Although this press is nearly superseded, it is desirable press. to point out its component parts, as they indicate the general principles on which all typographic machinery is based. The flat plane on which the type is laid is called the *bed* of the press; the other flat plane which moves vertically and presses the paper on the type is the *platen*. These are the two essential parts of the press. The platen is perfectly smooth and level on its under surface, in order to give the whole of the type forme an equable pressure. It is mounted in a strong iron frame, with a cross-piece or head. The platen is propelled by a piston, which moves up and down. The power is gained by bringing an inclined bar of steel perpendicular to the direct line of pressure, and in doing so the piston is forced down. This steel bar is the *chill*, shaped like an elbow. At one end is a bar or handle which, on being pulled towards the operator, straightens the chill or brings it into the vertical position. At the sides are guide-plates fixed into the frame, to preserve the parallelism of the platen, for the slightest vibration or lateral movement would prevent a clear sharp impression being taken. There are appropriate appliances, such as a helical spring, fixed on the head of the press, whereby the platen raises itself when the pressure is not required. In order to bring the forme readily under the platen, and to withdraw it so that it may be inked and the sheet to be printed placed in position, the table is mounted on a carriage, that runs on two rails by turning a handle connected with two endless bands. The paper is fixed to certain marks on the *tympam*, a kind of metal frame hinged on to the carriage, when it is in a sloping position. This ensures the paper being printed in the exact place required. The tympam, over which calico or parchment is stretched, is double, and contains within it a pad of paper or a piece of blanket, to moderate the force of the impression of the platen. To it is hinged another metal frame, the *frisquet*, which is covered with paper, cut to correspond with the shape of the type forme on the press. The ink is applied with a cylinder or *roller*, which revolves in an iron frame, and is

covered about an inch thick with a composition of glue and treacle or of glycerin or other substance. The ink is spread out with a palette knife or similar appliance on a table adjoining the press, and by repeatedly revolving the roller over it, it becomes coated with an extremely thin film of ink. The roller is then moved over the surface of the forme on the press, until sufficient ink has been transferred to it. This is called *rolling*, and is a very important part of press-work, for if inefficiently performed there will be too much ink on

FIG. 10.—Allion press.

the impression, or even blotches, which are called *monks*, or the print will be too pale or grey in places, such imperfections being called *friars*. The sheet of paper to be printed is next laid on the tympan, to pins serving as guides. The frisket is folded down on the tympan, which is in turn folded down on the forme with the right hand, while with the left the handle is turned and the press carriage brought under the platen. The bar is pulled by the right hand, the handle turned the reverse way with the left hand, the carriage brought out again, the tympan raised, the frisket opened, and the printed sheet removed, the tympan being ready to receive another white sheet. The frisket serves, among other things, to keep the edges and parts of the sheet not required to be printed from being discoloured by contact with the ink or the sides of the forme, and to aid in steadying the sheet when the tympan is depressed and in the removal of the sheet when it is raised. Such is a bare outline of the method of printing at a hand-press,—one necessarily imperfect from a technical point of view, but sufficient to indicate the essentials of the operation.

Another press which has been much used is the Columbian,—a name given to it by its inventor, Clymer, an American. The power is gained by an ingenious combination of levers. Two of these are connected by a rod with the bar handle, which is in itself a lever. The platen is attached to the head by a strong iron bolt, the descent being made steady and regular by vertical guides. It is counterbalanced by a powerful lever or beam, having an adjustable weight shaped like an eagle, which raises it automatically. In the bar handle is a screw stop by means of which the length of the lever rod can be adjusted and its pressure, or the *pull*, perfectly regulated.

Nine distinct processes have thus to be gone through in order to print one side of a sheet of paper at a hand-press:—(1) inking the roller, (2) inking the forme, (3) laying the sheet on the tympan, (4) folding down the tympan, (5) running in the forme under the platen, (6) taking the impression by depressing the platen, and then immediately afterwards allowing it to raise itself by means of the counterpoise or spring, (7) running out the forme, (8) lifting the tympan and frisket, and (9) removing the sheet. The object of successive improvers of the printing press has been to render the apparatus more automatic, or to substitute for it a "machine" that will reduce these nine operations to the minimum. In modern machines this has been effected to the extent of rendering necessary only three of them—(1) laying on or "feeding" the sheets, (2) applying the motive power, (3) taking off or delivering the sheets; and rotary machines both feed and deliver themselves automatically. Nearly all cylinder machines have a delivery apparatus, and quite recently an appliance for the automatic feeding to them of single sheets of paper has been invented.

With respect to the platen press we notice first that which is capable of being driven by a rotating shaft or wheel. It should be observed that the adoption of the rotatory principle was essential to the acceleration of speed. This was recognized by the projector of the machine¹ press, William Nicholson, and by Frederick Koenig, who first brought the invention into use and constructed a practical

press. The essential arrangements of every machine are four, their respective objects being (1) to feed in the paper, (2) to ink the forme, (3) to print the sheet, and (4) to deliver or take it off.

The treadle platen press is the simplest of machine presses capable of being worked by a wheel. When other motive power is not platen available it is driven by a treadle, like that of a lathe. The type forme is usually secured by clamps on an almost vertical bed (fig. 11), and the platen rocks backwards and forwards, being thus brought in contact with the type on the bed. Just before the impression is taken, the two surfaces are momentarily parallel. The inking is effected by small composition rollers, adjusted in a roller carrier swinging on a pivot. The rollers receive ink from a "fountain" or duct of ink at the top of the machine, below which is an arrangement, such as a revolving disk, for distributing the ink. The constant motion of the rollers and of the revolving ink disk is equivalent to the manual movements of the operator who "rolls" at the hand-press. The rollers are carried by self-acting appliances over the face of the forme, and return to the ink table to be replenished with ink, after which the impression takes place. The sheet to be printed is placed in proper position on the platen, which is covered with paper or parchment, and is secured there during the movement of the platen by movable fingers called *grippers*. The platen on advancing brings the paper in contact with the type forme; after the printing it returns to its original position, when the sheet is removed and another sheet adjusted ready for being printed. The treadle platen press is only adapted for work on paper of small size, up to half sheet demy, but within this limit it is greatly superior to the hand-press. If sufficiently strong and well built, it gives a far more powerful impression, and it occupies about a sixth of the space. Its great merit, however, is its superior speed. The hand-press, when worked by two men, one rolling the types and one pulling the handle of the press, produces only about 250 impressions per hour. The treadle press is worked by a boy, who has only to depress the treadle with his foot, and lay on and take off the sheets with his hands, and he can work at the rate of more than 1000 per hour. The treadle press is also superior to the hand-press in the uniformity of its results, since the automatic inking ensures a greater regularity in the colour of the impressions than with the old hand-inking process.

FIG. 11.—Minerva press.

The ordinary or "double" platen press was, in principle, very similar to the hand-press. It was about 13 feet long. The platen, in the centre, was massive, as the machine printed sheets as large press. as double demy, and it had a perpendicular motion, being guided in grooves and worked by a connecting rod fixed to a cross beam and crank, which acquired its motion from the main shaft. In other respects the machine differed from the hand-press in having two type beds or coffins and two inking tables arranged at the ends of the carriage, which travelled backwards and forwards, being worked by a drum underneath. The paper to be printed was laid to marks on the frisket, and this was hinged on the tympan, which in turn was fastened to the end of the coffin by hinges or joints. The frisket and tympan were opened by running up bars at suitable positions. After a newly printed sheet was removed, another was placed on the frisket, which as the carriage moved ran down the bars and closed on the sheet, which then received its impression. This arrangement was dangerous to the boys who had to lay on the sheets.

Formerly it was thought that the very finest printing could not be done by a cylinder impressing a forme in the progress of its reciprocating motion, for that was liable to slur or blur the impression. Hence platen presses were employed for the best work. Of recent years engineers have brought the cylinder press to such perfection that there is not the slightest danger, under the superintendence of a capable man, of any slur. Working quite as well as the platen press, the cylinder press is enormously quicker and more productive; it requires less driving power; and much better inking is obtained, which is all-important for fine woodcut printing. Accordingly, for even the best illustrated book-work, the platen power-press is now almost entirely superseded by the cylinder.

Cylinder machines are of two kinds,—(1) presses in which the type is on a flat plane and (2) those in which the type, or more correctly the impressing surface, is cylindrical. The first are called *cylinder* presses, the second—a development of the first—the *rotary* web presses.

The simplest kind of mechanical press is called the single-
XXIII. — 89

¹ The best account of its invention is contained in a series of articles by Mr William Blades in the *Printers' Register*, 1883-84, and Th. Goebel's *Friedrich Koenig und die Erfindung der Schnellpresse* (Stuttgart, 1883). This last has been translated into French by Paul Schmidt, *F. Koenig et l'invention de la Presse Mécanique* (Paris, 1885).

Single-cylinder or one-sided machine, which has been recently brought to the highest state of perfection by Mr Samuel Bremner. It is generally used for commercial and fine book-work on one side of the paper. There are different varieties of cylinder machines, distinguished by trade-marks or the names of their makers; but the general principles, apart from details, are practically identical. There is a strong cast-iron frame, with bearings to carry the cylinder, which runs across the machine transversely, nearly in the centre. The cylinder revolves by gearing connected with a main shaft, which also works the other moving parts. This shaft is turned by a wheel for hand or steam power. The table for

upon the tympan and folding it down on the forme are superseded by the presentation of the paper to the grippers; and the taking-off of the sheet after raising the tympan is superseded by removing it when released by the grippers and laying it on the adjacent table,—both immeasurably easier operations and done much more rapidly. Indeed both laying-on and taking-off may be done automatically, as is explained below. The result is that, while two men are required to print a sheet of book-work on one side of the paper at

the speed of 250 an hour at the hand-press, machines of this class worked by one operator print about 1200 per hour. Even

FIG. 12.—Extra-colour Bremner machine, with sheet-flyers.

carrying the type is also provided with a flat inking board of wood or iron, used for distributing the ink. It travels backwards and forwards, that is, with a reciprocating motion. At one end of the machine is the *feeding-board*, on which the pile of paper to be printed is placed. The layer-on places each sheet against metal marks, consisting of rectangular pieces of steel or brass mounted on a bar underneath, which rises and falls according as the sheet is being laid to and taken away from them. When placed against these marks, ensuring correct "lay," the sheet is seized by grippers or light metal claws fixed on a bar inside the cylinder. These clutch the sheet and carry it forward round the cylinder, which in its revolution brings it forcibly in contact with the type forme moving forward underneath, when the impression is effected. Immediately after the grippers release their hold, and the sheets are removed singly by an attendant called a *taker-off*, or by a mechanical automatic arrangement called a *flyer*, and deposited on the taking-off board. At the end of the machine farthest from the laying-on board is fixed a trough, which contains the ink; it is fitted with the *duct roller* of cast-iron, which revolves by means of a band or ratchet-wheel and pawl. A flat bar or knife with a thin edge is set up against the metal roller lengthways by adjusting screws, which regulate the passage of the ink, and permit a thin film to pass the knife. A composition roller, called a *vibrator*, is fixed underneath, which takes off the ink that has already been deposited on the duct roller and leaves a ridge or strip of it on the inking slab. As the carriage returns, this strip of ink is distributed on the inking table by rollers placed diagonally across the machine. The diagonal position gives them a waving motion; hence they are called *wavers*. The inking of the forme is done by another set of rollers called *inkers*, placed near the impression cylinder. The inking rollers receive their ink from what is distributed on the table and coat the type while it is passing underneath them.

Thus the nine operations of the hand-press requisite to print one impression are greatly reduced. The bed carrying the type to and fro from the point of impression moves mechanically, superseding the running in and out of the carriage by the rounce and handle of the hand-press. The inking table, although independent, forms part of the type table, and some of the rollers distribute and others ink, this again being done mechanically and without a second operator. The platen and the tympan, as well as the levers by which the impression is given, are in effect combined in the cylinder, which rotates by gearing, the pressure being applied during the motion of the table itself. The laying-on of the sheet

ductiveness of the machine to the press would be, per hour, about 8000 to 250.

As already mentioned, a self-acting feeding apparatus has been invented for supplying single sheets to cylinder machines. The pile of paper is laid on a feeding board or table, between gauges. A pneumatic tube takes up one sheet at a time; it is then run down tapes to a point at which india-rubber fingers bring it to the side lay of the machine, and it is printed with perfect accuracy of register. Once started, the machine works automatically, and the services of both layer-on and taker-off are dispensed with.

We may now describe that class of machines by which the paper Perfect is printed on both sides, or perfected, during one passage through the machine. The Applegath and Cowper or ordinary machine presses, has two impression cylinders, having a continuous rotary motion towards each other. The frame is necessarily long, usually about 15 feet, and the width of the machine about 5 feet, these dimensions depending upon the size of the sheet to be printed. The table or carriage is double, containing two beds for the two formes of type, to impress the two sides of the paper, and two distributing tables for the ink. At each end is a complete roller apparatus, consisting of duct, duct roller, vibrator, and wavers. Close to the large cylinders on each side are the inking rollers. The table has a reciprocating motion, as in a single-cylinder machine. The distinctive feature is the ingenious manner in which the sheets are printed first on one side and then on the other. This is effected by carrying them over cylinders and drums by means of tapes. The pile of sheets stands on a high table placed at one end. The sheet is fed into the apparatus and led round an entry drum; thence it is carried round the large right-hand impressing cylinder, and underneath this, on the table, which is moving at the same speed as the cylinder, is the inner forme properly inked. The paper thus receives an impression on one side. It is next led up to the right-hand drum, which it passes over, the printed side of the sheet being then downwards. Continuing, it is brought under the second or left-hand drum and on to the left-hand impression cylinder, which it passes with the printed side still downwards, or next to the cylinder, exposing the other side to the type of the outer forme on the table underneath. The drums have thus reversed the position of the paper: the side which was outside when passing the first forme is inside when passing the second forme, which accordingly prints the sheet on the opposite or blank side. The sheet is finally run out by the tapes and delivered in the space between the large cylinders, seized by a taking-off boy, and deposited

this comparison does not convey a complete idea of the enormously increased productiveness of the cylinder machine over that of the press. By the latter, the largest sheet practically that could be printed was double demy, 23 x 35 inches, the superficies of which is 805 square inches; single-cylinder machines are now made to print eight sheet double crown, the superficies of which is 4800 square inches. These sheets being afterwards cut up into double crown sheets, the pro-

on a table or taking-off board. This press is known as the *drop-bar perfecting machine*, owing to a peculiarity of the arrangement by which the paper is conveyed into the tapes. In front of the feeding table is a rod or bar of steel, along which are fitted several metal disks or bosses about half an inch thicker than the bar itself. These can be shifted, by means of small screws, to any position along the rod to suit the size of the sheet to be printed.

To this bar is fixed a short arm, with a pulley at the end, which works round a wheel attached to a cam with a dip. Every time the pulley drops into the dip, the bar descends upon the paper, which is laid to marks at the front; and the bar, possessing a rotary motion from the tapes, runs the sheet between a roller

and a small drum on to the inner forme cylinder, as already stated. Other kinds of machines are distinguished as the web, having a web or a series of broad tapes which lie on the laying-on board and are fastened to a small drum underneath it. The drum has a series of small cogs, and when it is forced forward it moves the web or tapes in the same direction. The sheet, having been laid to a back mark on the tapes, is propelled between two revolving rollers and thus taken into the machine.

There are several distinct types of perfecting presses in use, but we can only notice one or two. In the Anglo-French machine, which was invented in England but improved in France, grippers are used instead of tapes and

FIG. 13.—Marinoni combined perfecting and duplex single-cylinder machine.

the intermediate drums for conveying the sheet from one cylinder to the other. The cylinders are on a level, but alternately rise and fall, allowing the sheet to clear the forme. Quite recently a single-cylinder perfecting press has been invented. The cylinder is double the usual size and has two printing surfaces and a double set of grippers. Two sheets are printed at each revolution, the first being the white paper and the second the partly printed sheet which has immediately preceded it. The sheet is fed in as to an ordinary single side press, printed on one side, taken off, reversed, again gripped, and perfected, when it is automatically delivered on the table.

It has been mentioned that 250 sheets or a *token* per hour, printed on one side only, represent the work of two men at the hand-press. Two youths at a perfecting machine will complete from 1200 to 2000 copies per hour, equal to 4000 impressions on

one side only,—an increase of about sixteenfold. This, however, does not represent the whole of the superiority of these machines. Sheets much larger than double crown (20 × 30 inches) can hardly be worked at a press; the machine perfects a sheet nearly double this size—50 × 40 or four royal, so that the proportionate product of the machine to the press is about as 32 to 1.

Perfecting machines are not so much used for book-work as formerly. The single-cylinder machine has been brought to such perfection, and is so superior in its inking arrangements, that printers prefer it. In America nearly all machines are one-sided. For newspapers of limited circulation, however, the perfecting machine is well adapted. Complete copies of a journal are produced as soon as the machine is started; extra copies can be worked off while news-agents are waiting; and a number of sheets need not be printed off on one side to be completed when a sudden demand arises.

Fig. 13 shows a new form of French perfecting machine for printing book-work, the Marinoni com-

FIG. 14.—Walter machine.

combined perfecting and duplex single-cylinder machine. The improvement in this machine over the perfecting two-cylinder machine described above consists in the alteration of some mechanical parts, so that the same machine can be used for printing sheets either on both sides or on one side only. It therefore serves the purpose of two single-cylinder machines or of one perfecting machine, the change from one to the other being very simple.

Rotary press.

The rotary press differs essentially from the cylinder machine. In the former the printing surface and the impressing surface both rotate continuously, and the paper,—not cut up into single sheets, but carried between the two cylinders in a roll or web, like a ribbon,

—receives successively an impression on each side, after which it is cut up into sheets of the proper size and folded as it is run out, the sheets being deposited on a table ready for removal.

As representative of this class of machines we may take the Walter press, whose mechanical arrangement is shown in fig. 14. The paper to be printed from, a continuous web about 8000 yards in length, is wound on a small roller at P. It is passed over a tension roller, and then over the damping cylinders W, W, and thoroughly wetted on both sides. The damping cylinders are hollow, and contain sponges from which the water is distributed by centrifugal force, the outside of the cylinder being covered with

blankets. The paper next passes on to the printing cylinders *T, T'*, on which the printing surface—not composed of movable types but of stereo plates—is fixed, and to the impression cylinders *I, I'*. The printing cylinders contain each the plate in curvilinear shape, constituting the forme for one side of the paper. The web is led between the printing and the impression cylinders, as shown by the dotted line. After being printed on one side by *T*, it travels round *I* and receives an impression on the other side from *T'*, thus being “perfected.” It then passes on to the cutting cylinders *K, K'*, one of which has a serrated knife, which enters the paper, and on the application of tension divides the web, causing the peculiar saw-like edge seen in copies of journals printed on rotary machines. The paper is next carried in over tapes to the point where the complete severance takes place. Soon after they encounter a pendulous frame, which delivers them in two piles on to the tables *a, a'*, whence they are removed. There is an ink supply trough *a*, which is connected with the distributing rollers by a revolving metal roller *b*. The distributing rollers of metal are marked *f, g, h, i*, and the rollers which ink the forme, made of the ordinary composition, are marked *k, k'*.

The average rate of speed of the Walter press is 12,000 per hour, the sheets being printed on both sides. In this apparatus everything is automatic: there is self-feeding and self-delivery, the web of paper at one end being transformed into properly printed single sheets at the other. The machine requires only one man to superintend its general working, including the replacing of the web when printed and the removal of the successive piles of sheets. In respect of speed, if the perfecting machine is to the hand-press as 32 to 1, the rotary will be to the hand-press as 96 to 1. The Walter press, requiring a space of only about 14 feet by 5, is not more remarkable for its speed and economy than for its simplicity of construction and its compactness. And the same remark applies to several other machines, such as the Victory, the Hoe, and the Prestonian, which have since come into use. Their general appearance is that of a collection of small cylinders or rollers, through which the paper seems to fly at railway speed, issuing forth in two descending torrents of sheets accurately cut into lengths. Without such machinery the prodigious issues of some of the morning journals would not be possible. One daily paper averages a circulation of more than a quarter of a million. This enormous number of sheets are printed in about four hours, owing to the type matter being stereotyped and placed on several presses.

Printing from webs of paper. Printing from webs of paper instead of single sheets will probably be adopted in the future for all newspapers and even books of large circulation. Hand-feeding is limited by the ability of the operator to lay the sheets on the feeding-board with the necessary accuracy. One chief obstacle to the more general adoption of rotary printing is the expense of stereotyping the type formes. Although a machine has been constructed in which movable types can be placed round the periphery of an impressing cylinder, it cannot compete with the Walter and other presses using stereo plates. The problem of printing directly from flat formes of ordinary types, as well as from stereotypes, with paper supplied in the roll, is one that may be commended to engineers. The saving in stereotyping in many cases would be very considerable; but, even where this is not an object, the readiness and ease with which the type could be manipulated would ensure for such an apparatus admission into offices where the large rotaries of the present day are inadmissible. It would also enable illustrated journals to be printed from the web. The pictures introduced into some of our daily journals are very rude when compared with those in periodicals printed on flat-bed machines. This is owing partly to the distortion that arises when the cast from a flat block is accommodated to a curved surface, partly to the fact that stereotyping does not give the fine and delicate reproduction that electrotyping supplies, and partly to the imperfect inking powers of the machines. Quite recently a plan has been patented whereby curved electrotypes of pictures can be fastened to blank or depressed portions of an ordinary curved stereo plate; but the method is not always practicable. With a flat-bed machine the forme to be printed from might be of a composite kind,—partly movable types, partly stereotype, and partly electrotype. One difficulty of constructing a web printing machine with a flat bed is that of turning the sheet so that it may be printed almost simultaneously on both sides. It would have to be reversed by the continued rotary movement of the cylinder. This, however, is quite within the limits of practicability, and experiments are now being made to devise a machine with this feature.

Roller composition. For about three centuries after the invention of printing the formes were inked by leather balls. When machine presses were introduced, their earliest inventor tried to use cylinders covered with leather; but the plan was most unsatisfactory, until a subsequent inventor adopted a composition of glue and treacle, which was cast into cylinders having an inner “stock” of metal or wood. For about half a century this composition was used exclusively for both hand and machine presses. Since then glycerin has been introduced for roller making. Hansard’s recipe, in use when the 8th edition of the present work was issued, was—glue 4 parts,

treacle 12 parts, Paris white 1 part. But a much better composition is now formed of glue 10 parts, sugar 10 parts, and glycerin 12 parts. The glycerin has the property of always keeping the roller moist and soft, while the tendency of glue and treacle is to dry and harden. A glycerin roller lasts much longer than one of glue and treacle.

Printing ink has peculiar qualities. It is required to change from the soft adhesive state in which it is applied to the type to that of a perfectly hard and dry substance after being transferred to the printing ink. This change of condition must be under control, and when air is excluded the ink should keep in good order any length of time. During its application to the type its solidification should be as slow as possible, and unaccompanied by the emission of any unpleasant or deleterious odour. It ought not to affect the rollers, and, having been applied to the paper, its action should be confined to a very slight penetration, just sufficient to prevent its detachment without injuring the surface of the paper. It must dry into a hard, inodorous, and unalterable solid. The ingredients of ink are burnt linseed or other oil, resin, and occasionally soap, with various colouring matters; that for black ink is usually lamp black, but charcoal and other cheaper materials are occasionally introduced. Ink is removed from types and blocks by detergents, such as potash and pearl ash; benzine is also well adapted for the purpose.

Colour Printing.

The apparatus previously described is intended for monochrome printing, whatever be the shade of the ink. When two colours or in two more have to be printed in one composition, there must be a separate type forme or separate engraving, and a separate printing, for each. Many attempts have been made to print several colours simultaneously by dividing the trough or manipulating the rollers. All these have been more or less unsuccessful, with the exception of a press invented by Mr W. Conisbee, which prints from type formes in two colours. In construction it is somewhat similar to the ordinary single-cylinder machine, but is provided with two sets of inking apparatus, including ductor, wavers, and inkers, each of which acts totally independent of the rest. The cylinder is placed in the centre of the machine and makes two continuous revolutions, giving an impression for each colour. There are two type formes, each containing only the lines to be worked in one of the colours. These are in two beds adjoining one another, and, the circumference of the cylinder being equal to the length of one bed, one colour is printed by the first revolution and the other by the second. The sheet is thus printed twice without being released from the grippers, whereby perfect register is ensured. The speed is slow, averaging 300 to 400 complete impressions per hour.

The method by which the beautiful coloured supplements issued Chromo-occasionally with illustrated newspapers are printed may be slightly typographical referred to. A copy of the artist’s painting is first of all made, on graphy. a scale regulated by the size of the reproduction. This being supplied to the engraver, an outline or key block is made and proofs pulled. It is now necessary to determine the tones of colour to be used,—a process demanding great experience. The key block will, if printed first, afford a guide for the registration of the subsequent printings; sometimes, however, that is reserved for a later stage. The colours on which the subsequent printings are done must be of a transparent nature. The blocks are sometimes produced by the typographic etching process, which gives a softness, delicacy, and variety unattainable by the graver. The blending of the colours is the most delicate task the printer has to undertake. A large picture is often printed in ten or more workings, some of them in their turn intensifying and bringing previous colour workings into stronger relief, others giving shape and form to the picture. Almost to the end of the process, however, the picture will want vitality; its outlines will be hard and bare, or vague and undefined, according to the sequence of the colours. Another working may give grey tones where wanted, and may increase the depth and transparency of various parts. A deep flesh working may have a marked effect on the development; and, near the close of the series, if the entire colouring is found to be too warm, it may be corrected by over-printing very nearly the whole subject. Chromo-typography has undoubtedly made great strides during the past twenty years, its best results being shown in the coloured prints for illustrated journals. For the production of pictures for commercial and artistic purposes chromo-lithography Chromo- is generally resorted to on account of its relative economy. In litho-lithography for typographic purposes the line has to be cut and the graphy. space on both sides removed so as to leave the line alone to be charged with the ink, or the white space has to be etched away with an acid. The printing of isolated points too is easily effected from a stone, whereas most minute labour is necessary to engrave them. Typographic etching has here, however, been of great assistance. The differences of printing surface caused by the colours are met and overcome by the lithographic stone with great facility, even when the spaces are largest and most uneven; it is quite the contrary in regard to typography, wherein the work has to be charged with ink to a greater extent according to its size, and the quantity

of ink requisite varies with the fineness of the strokes and of their distance apart. Owing to this we see in most letter-press polychromatic prints a deficiency of transparency, of half-tints, of depth of ground, and of general harmony. Even if it were possible to make chromo-typography as easy as chromo-lithography, there would still be the obstacle of its very much greater cost, owing to the expense of the engraving and of the casts from the key block. In chromo-lithography the designer can repeat the designs for the different stones by a process that costs almost nothing. Also in the process of multiplying the blocks the deviation in the register of the successive colours is practically unavoidable. In lithography the surface to be printed is nearly level; hence the sheet is not shifted and twisted or stretched in places, as it is in typography, owing to the alternate closeness and absence of contact between the sheets and the raised and depressed surface of the block. Whatever success the letter-press method has attained of late is owing to the invention of electrotyping and process blocks, and to the improvement of machinery. For to print these pictures enormous strength and rigidity, and the most perfect arrangements for securing register, are absolutely essential.

Recent Changes.

Progress in printing. We will now give a cursory glance at the changes that have been effected during the last twenty-five years in the processes and the products of the art of printing. That these have been of a most drastic kind may be gathered from a comparison of the appliances figured and described in the 8th or the previous editions of the *Encyclopædia Britannica* with those referred to above. The hand-press has been almost completely superseded by the machine press. Cylindrical impression has displaced platen impression, and the finest book-work and woodcut work are done on a cylinder press. In book-work, indeed, other significant changes have taken place. Whereas formerly it was deemed essential that the paper should be damped before printing, in order to get a delicate and perfect impression, some of the finest books and periodicals are now printed on dry paper, highly calendered, even the illustrated journals and some of the evening papers being so worked. Then, it was thought necessary for the safety of the type to interpose a thick soft blanket between it and the pressing surface, whether cylinder or platen; now, it is found equally safe, and far more conducive to a good impression, to make the packing as thin and hard as possible. Then, fine woodcuts were "brought up" by the use of many "overlays" and "underlays" to correct inequalities in the surface of the blocks and emphasize some of the parts; now, although the art of "making ready" has been brought to great perfection, the fewer and thinner the overlays employed the better. And it may not be irrelevant to point out that the printing of woodcuts has improved in the same degree as the engraving of them.

Improvements in newspaper printing. Perhaps, however, the most remarkable change is that made in newspaper printing. The highest achievement mentioned in the article "Printing" in the 8th edition of this work was the six-cylinder Hoe machine. The makers of that apparatus subsequently contrived machines of eight and ten cylinders. But they have now been wholly superseded by the rotary presses on the Walter principle. The hand feeding-in of single sheets is entirely done away with, and all newspapers of considerable circulation are printed from long reels of paper, uncut, as originally made at the paper-mill. The maximum number of copies which a machine of this class would print with ten feeding attendants and four taking away attendants would be 8000 an hour. For folding the 8000 printed copies five folding machines and at least two attendants would be required to keep pace with the printing machines. Thus nineteen men were required to print and fold 8000 copies per hour with the best machines as late as 1870. With a rotary machine doing the same or a larger quantity of work only two men are required. The cost for printing and folding 1000 copies by the Hoe machine was estimated at 1s. 4d., while with the rotary it is only about 2d. Hence the saving of wages to a newspaper issuing 200,000 copies a day on 313 working days would be nearly £3700 in a year. This, in connexion with improvements in paper, or rather the discovery of cheaper materials, bringing the price of "news" down to about 2d. per lb.—one quarter of its price a very few years ago—accounts for much of the enterprise of modern journalism. For some time after the abolition of the paper duty there was a loss on the circulation of a large-sized penny journal; now there is a considerable gain. Lately rotary presses for small jobbing work have been constructed; and before long the rotary principle will probably be rendered available for illustrated periodicals and fine book-work, printed from webs or reels of paper instead of single sheets. Great improvements have also been made in type-founding, and the Roman and Italic founts now used by English printers are equal to those of any country in the world. It is sometimes said that English *éditions de luxe* are not equal to those of the French, and that this is owing to the inferiority of the founders. This is, however, not quite true: some of the best French books are printed from English types or from types cut in the English manner. It is also the fashion to compare modern printed books with those of the Elzevirs

and Baskerville. Yet as a matter of fact their best faces have been reproduced with perfect success by modern founders. From a mechanical point of view the impression given by the best machine presses to-day is undoubtedly superior to that of the hand-presses of the 17th and 18th centuries. If modern books suffer in any respect on comparison with those of former times, which are so highly prized by bibliophiles, it is owing to their want of general artistic *ensemble*, and not to any deficiency in mechanical execution. The artistic taste of English printers has, however, been greatly raised during the last few years, and a very interesting movement is going on which must produce important results in the future. In 1880 Mr Andrew W. Tuer of London organized the Printers' Specimen Printers' Exchange, a scheme intended to promote the technical education Specimen of the working printer. Each contributor to the exchange furnishes men Ex-periodically a certain fixed number of typographical specimens, all change, alike, which are collated into sets, and again distributed to the members, each of whom gets a volume, consisting of one copy of the work of each of his fellow-contributors. By this plan they become acquainted with the progress made by their brethren, and good taste and good work are fostered and mutually encouraged. The eighth quarto volume, issued in 1887, contains nearly 400 fine specimens of typography by as many different hands. It forms also the best criterion of the character of the jobbing work done at the present day, not only in England but abroad, for the scheme is of an international character. The results of the revival in Artistic artistic printing during the last decade are especially noticeable in printing, jobbing work. Much of this improvement is due to the superior material with which the printer is furnished, and especially to the great variety of ornamental types which have been introduced. The specimen books of the principal type-founders are splendid volumes, containing several thousand different faces. The best work of German printers is noteworthy for its studied neatness and attractiveness, tasteful and harmonious arrangement of colour and tint, a characteristic and conscientious attention to details of finish, exact register, and beauty of impression. American work excels in originality of design, brilliancy of colour, and perfect finish. English printers are closely following the best points of each of these schools of typography. There is a distinct leaning at present to the German style, but with little slavish imitation. The distinctness of English typography is maintained, while the beautiful German combination borders, produced with such profusion of late, are judiciously utilized, often in conjunction with American type. In the arrangement of colours English printers prefer the quiet harmonious tints of the Germans to the bold striking contrasts of the Americans.

The vast extent of the operations of the printing fraternity Division at the present day is in remarkable contrast to those of the 15th of century, when the making of books was an art like the sculpture labour of statues or the designing of buildings. Now, printing is a manufacture in which large capital and the greatest division of labour are essential. The old printers were almost entirely independent of other craftsmen. From the casting of the type to the mixing of the ink they did nearly everything for themselves. Gradually the different departments of the art were constituted separate and recognized trades. The type-founder was probably the first to secede from the concern; then printers delegated to others the making of presses; afterwards the ink and the rollers found separate and distinct manufacturers; and there arose a class of persons who, though belonging to other trades, made printing appliances a specialty, such as printers' smiths, printers' joiners, and printers' engineers. Subdivision again has taken place in regard to the operations which chiefly appertain to printing. The same man was formerly able to set up and print off the types, to fold the sheets perhaps, and even to make them up into books. The operative printer has now become either a pressman or a compositor. If he is of the first denomination, he may be classed according as he works at press or machine. If he is a machinist, he may superintend or be a "minder," or he may be a layer-on or a taker-off of the sheets. If he is a minder, he may understand only book machines or only news machines; he may know all about platens and little about cylinders; or of cylinders he may know only one kind. Entirely novel machines create a new class of artisans. There are men perfectly competent to manage a Walter press who are ignorant how to work two-colour or fine book-work machines. In the compositor's department division of labour is carried out to a still minuter degree. An old-fashioned printer would set up indifferently a placard, a title-page, or a book. At the present day we have jobbing hands, book hands, and news hands, the word "hand" suggesting the factory-like nature of the business. There are jobbing hands who confine themselves to posters, and know little about general work even in this department. Book hands comprise those who set up the titles and those who set up the body of the work. Of these latter again, while one man composes, another, the "maker-up," arranges the pages. Even the art of fitting up the furniture or "dressing the chase" is given to the "quoin-drawer overseer." News hands include advertisement hands and general hands. Some men work by day, others altogether by night; some do general

book-work composition; others set up head-lines; others make up the galleys; others "prove" them.

Old Style Printing.

Old style printing. Within the last few years there has been an interesting revival of the old style of book printing. It owes its origin to Mr Whittingham of the Chiswick Press, who in 1843 was desirous of printing in appropriate type a work of fiction the diction of which was supposed to be that of the reign of Charles II. As the original "old face" matrices of the first Caslon had been preserved, a fount was cast from them, and on getting a proof with good ink, on good paper, from a modern press the impression was found to be far superior to specimens printed from the original fount. Since then the demand for old-faced characters has steadily increased, and all foundry now supply imitations of the old types. Comparing the old face and the modern characters, the latter are more regular in size, lining, setting, and colour,—using these words in the technical sense of the founder; they have finer strokes and serifs, and produce in the page a more regular and sparkling general effect. At the same time it may be conceded that legibility has been to a certain extent sacrificed to beauty and general effect. About 1882 an eminent French printer made a number of experiments to ascertain what it is that constitutes legibility in type, and found that people read with less fatigue according as the letters—(a) are rounder, (b) are more equal in thickness, (c) have shorter upstrokes, (d) are dissimilar to each other, and (e) are well proportioned to their own body. Drawings of letters from old books were visible and legible at a distance at which modern letters could not be distinguished. The revival has also brought about the re-introduction of antique head-pieces and tail-pieces, vignettes, and initial letters, which have been reproduced from old books by photography and type-setting. For this kind of printing white paper has given place to toned, of a straw tint, which is often more agreeable to the eyes than the excessively bleached paper which was hitherto the fashion. Also hand-made instead of machine-made paper has to a large extent come into vogue. Its characteristic is the "deckle edge", which distinguishes it from the clean-cut edge of machine papers, and is highly prized by some bibliophiles. When extreme verisimilitude is required, this kind of printing is done on the blank leaves of real old books, some of which have been ruthlessly destroyed for this modern craze. On the whole, however, the revival of old style printing has been beneficial: it has encouraged printers to study the more artistic attributes of the productions of the great printers of the past, and has educated the public taste by presenting them with examples of the best kind of book-making.

Printing Establishment.

Departments of printing. A large book-printing establishment contains many distinct departments, some of which have not been previously referred to and may here be summarily mentioned. The reading department, sometimes called the *closet*, consists of a number of small apartments, each furnished with a desk, a couple of stools, and a shelf for books of reference, and having for its occupants the reader and his reading-boy. There is also the warehouse, where all the printed and unprinted sheets (or "white paper" as it is called, whatever its colour) are stored. Adjacent to this are folding, cutting, hot and cold pressing, drying, and other branches, each employing separate classes of artisans. Another department is the machine-room, where, arranged in long rows with an avenue between, are the various printing machines. The men in this part of the establishment wear cotton vestments, covering all their other apparel, and caps, invariably made of paper, something like clerical birettas. The machine overseer has his box and keeps an account of the produce of each machine. Under him are the persons whose business it is to cut out overlays for the cut or illustrated formes. These men are in their way artists, for to them is attributable much of the beauty and perfection of working of each block that goes through their hands. They have by them three or four prints or "pulls" of the block, and their tools consist of scissors, paste, a sharp knife or two, and perhaps a razor-like blade set in a wooden handle. Their work is to deepen the shadows, raise the lights, lower the edges, and perform a hundred other offices for a block. Standing sentry over each machine is the machine minder; under him are the takers-off and layers-on. The engine-room and boiler-house are close by, and higher up may be the hand-press-room,—provided these appliances are used. Here are the pressmen and their apprentices. There is the storekeeper's department, fitted up with shelves, racks, and drawers, for the orderly storage of type and materials. The plate-safe or plate-room is the repository of the stereo and electro plates, each plate being kept wrapped up in paper, with a distinctive index number marked thereon. There are also rooms for casting rollers, stereotyping rooms, drying rooms for paper, hydraulic pressing rooms, sinks for washing formes, and lifts for conveying them

from one department to another. There will possibly be several composing-rooms, such as the *'stab*, where all the men are paid on established weekly wages, the piece room, where they are paid by results, and the apprentices' room. There may be rooms where particular jobs are done, especially if weekly periodicals are turned out, and the names of these designate the rooms. At the end of each room is the overseer. It is also a common practice for a Compositor number of men to form themselves into a kind of business partnership called a *companionship* or *'ship*. All the transactions of the partnership compositor may be with his own *clicker*,—the workman who is selected to keep the accounts of the partnership. From him the compositor receives his portion of copy and the necessary directions, and to him he gives the matter when it is composed. At the end of the week he "writes his bill," delivers it to the clicker, and from the latter receives at pay time the wages he has earned. The clicker gets the matter proved or "pulled" by the proof-puller, who usually does nothing else but pull proofs. He will then send the proof with the copy to the overseer, and the overseer sends it to the reading department to be corrected. The proof, when corrected, is returned through the overseer (who retains the copy) to the clicker, and he gives it to the compositor who set it up. When the type is corrected a revise is pulled, which goes through the same hands to the overseer again; and then it is despatched to the author, editor, or publisher. In a well-ordered composing-room strict silence is enjoined upon the workmen. Among the industrial pursuits there is none more monotonous and more exacting, none demanding more patience, sustained industry, and power of endurance than the compositor's art. In a large newspaper office the quantity of types picked up in a few hours is marvellous. No better illustration of this could be given than the fact that several recent issues of the *Times* have consisted of three sheets or twenty-four pages, each page comprising six columns. In one of these issues 84½ of the 144 columns were filled with advertisements, 2559 in number, set in extremely small type; the remaining 59½ columns contained articles, reviews, letters, reports, and paragraphs. The total length of the column aggregate was 264 feet (62 more than the height of the London Monument). If the matter comprised in the paper, instead of being broken up into columns, had been set in one continuous line it would have reached one mile 950 yards. The number of separate types used in printing this issue was calculated at over two millions, and the quantity of printed matter was reckoned to be equivalent to that contained in two octavo volumes of 480 pages each. The literary and mechanical staff of a first-rate London daily newspaper, excluding casual reporters and unattached writers on various subjects, aggregates about 300 persons.

Bibliography.—On the practice of the art and its auxiliary processes, see Southward, *Dictionary of Typography* (3d ed., London, 1875, 8vo); with the *Literary Artisan* by William Blades, and *Practical Printing: a Handbook of the Art of Typography* (3d ed., London, 1887, 2 vols., 8vo). This last is the fullest work on the subject in the English language, embracing composition, press work, stereotyping, and electrotyping, and the warehouse department of a printing office. Gould's *Letterpress Printer* (2d ed., Middlesborough, 1880, 12mo) has a short introduction by Southward, giving a sketch of the origin and progress of the different typographical processes and appliances from the beginning. See also F. J. F. Wilson, *Typographic Printing Machines and Machine Printing* (3d ed., London, 1883, 8vo); *List of Technical Terms relating to Printing Machinery* (London, 1882, 8vo); Noble, *Machine Printing* (London, 1883, 8vo) and *Principles and Practice of Colour Printing* (London, 1881, 8vo); and Wilson, *Stereotyping and Electrotyping* (London, 1880, 8vo). This last contains a history of stereotyping and electrotyping by Southward. The best works in French are—Lefevre, *Guide Pratique du Compositeur et de l'Imprimeur* (Paris, 1855-72, 8vo, two parts); includes machine work, stereotyping, and electrotyping; Claye, *Manuel de l'Apprenti Compositeur* (3d ed., 12mo, Paris, 1889); and Monet, *Les Machines et Appareils Typographiques, suivis des Procédés d'Impression* (Paris, 1879, 8vo). The best German work, and one which from its completeness surpasses all others, is Waldow's *Illustrirte Encyclopädie der graphischen Künste* (Leipzig, 1884, 1ar, 8vo), containing 2798 articles and 581 illustrations, with a list of German books on typography, &c.

Periodicals.—No trade or interest in the world has, perhaps, so many representatives in the press as printing. The journals which record its progress and describe its products are unrivalled in their excellent mechanical attributes, some equalling the highest class of book-work printing and using paper of the most luxurious description. Their literary character is usually worthy of their mechanical excellence, and they comprise an immense collection of facts and speculations on the subjects involved. They also attract a class of writers who in time become specialists and do the most valuable work in historical investigation. The *Printers' Register* (monthly), begun in 1863, the oldest of the English printing trade journals, contains several valuable contributions by Mr William Blades, the biographer of Caxton, such as "Numismata Typographica," "Bibliotheca Typographica," "Books and their Enemies," "The Inventor of the Steam Printing Press," and "Early Type Specimen Books." The *Paper and Printing Trades Journal* (quarterly), begun in 1872, is printed in old style fashion, and reproduces in tone as well as in manner some of the best examples of the French and Italian schools in head and tail pieces, vignettes, and ornamental initials. In France appear *L'Imprimerie* (semi-monthly) and the *Bulletin de l'Imprimerie*; in Germany, *Archiv für Buchdrucker-kunst* (monthly) and *Journal für Buchdrucker-kunst*; in Italy *L'Arte della Stampa*. The United States has the *Inland Printer* (Chicago) and the *American Bookmaker* (New York). The fullest list of such journals, past and present, is Louis Mohr's *Die periodische Fachpresse der Typographie* (Strasbourg, 1879). There is also an extended list, with historical annotations, in Bigmore and Wyman's *Bibliography of Printing*. (J. SO.)

TYR. See *ÆSIR*, vol. i. p. 211.

TYRE, the ancient *ṭy*, Greek *Τύρος*, the most famous

of Phœnician cities, is now represented by the petty town of *Ṣūr*, with about 5000 inhabitants, built round the har-

bour at the north end of a peninsula, which till the time of Alexander's siege was an island. The mole which he constructed to reach the island city has been widened by deposits of sand, so that the ancient island is now connected with the mainland by a tongue of land a quarter of a mile broad. The greatest length of the former island, from north to south, is about $\frac{5}{8}$ of a mile and its area about 142 acres, a small surface for so important a town. The researches of Renan seem to have completely refuted the once popular idea that a great part of the original island has disappeared by natural convulsions, though he believes that the remains of a line of submerged wall at the south end indicate that about 15 acres more were once reclaimed from the sea and have been again lost. Confined to this narrow site—on which, moreover, place was found for the great temple of Melkarth with its courts and for all the necessities of a vast trade, for docks and warehouses, and for the great purple factories which in the Roman time were the chief source of wealth and made the town an unpleasant place of residence (Strabo, xvi. 2, 23; Pliny, v. 76)—Tyre was very closely built; Strabo tells us that the many-storied houses were loftier than those of Rome. In the Roman period the population overflowed its bounds and occupied a strip of the opposite mainland, including the ancient Palætyrus. Pliny gives to the whole city, continental and insular, a compass of 19 Roman miles; but this account must be received with caution. In Strabo's time the island was still the city, and Palætyrus on the mainland was 30 stadia off, while modern research indicates an extensive line of suburbs rather than one mainland city that can be definitely identified with Palætyrus. The ancient history of Tyre has been dealt with in the article PHœNICIA; the topography is still obscure owing to the paucity of Phœnician remains. The present harbour is certainly the Sidonian port, though it is not so large as it once was; the other ancient harbour (the Egyptian port) has disappeared, and is supposed by Renan to have lain on the other side of the island, and to be now absorbed in the isthmus. The most important ruins are those of the cathedral, with its magnificent monolith columns of rose-coloured granite, now prostrate. The present building is assigned by De Vogué to the second half of the 12th century, but the columns must be older and may have belonged to the 4th-century church of Paulinus (Euseb., *H. E.*, x. 4). The water supply of ancient Tyre came from the powerful springs of Râs al-Ain on the mainland, one hour south of the city, where there are still remarkable reservoirs, in connexion with which curious revivals of Adonis worship have been observed by Volney and other travellers. Tyre was still an important city and almost impregnable fortress under the Arab empire. From 1124 to 1291 it was a stronghold of the crusaders, and Saladin himself besieged it in vain. After the fall of Acre the Christians deserted the place, which was then destroyed by the Moslems. The present town has arisen since the Metâwila occupied the district in 1766.

TYROL, a province of Austria, with the title of "county," lies between 10° 10' and 13° E. long. and 45° 40' and 47° 45' N. lat., and is conterminous on the north-west with the Austrian province of Vorarlberg, on the north with Bavaria, on the east with Salzburg and Carinthia, on the south-east and south-west with Italy, and on the west with Switzerland. The last-named country forms in the lower Engadine an angle penetrating deeply into Tyrol. The country is entirely mountainous, being traversed by the main chain of the Alps. It may be roughly divided into the valley systems of the Lech and the Inn to the north of the chain and of the Etsch or Adige (Vintschgau) and the upper Drave (Puster valley) to the south (see ALPS). Its area is 10,316 square miles; its population in 1880 was 805,176,

inclusive of military, showing an increase of nearly 4 per cent. since 1869. Of these 432,062 spoke German, 360,975 Italian or some Romance dialect, and the remainder some form of Slavonic; 565,468 persons were able to read and write, 56,728 to read only, leaving about 22 $\frac{3}{4}$ per cent. of the total population, including children, wholly illiterate. Education is strictly compulsory; but the schools are for the most part closed during the summer months, when all available hands are required in the fields and on the mountain pastures. Agriculture and forestry occupy about two-thirds of the entire population. Every householder owns a piece of cultivable land in the valley, while his goats, sheep, or cattle are driven with those of his neighbours to the mountain pastures (*Alpen, Almen*) which belong to the commune. Each commune has a president chosen by an elected committee of householders. The man selected cannot decline, but is bound to serve his term of office. The tenure of property is for the most part of the nature of absolute ownership. In 1880 100,393 persons of both sexes were returned as proprietors, 10,283 as tenants. The chief products are milk, butter, and cheese. Of grain-crops maize, which is largely grown in the Inn valley and Vintschgau, holds the first place. Wheat is grown in the lower valleys, barley and rye in the higher, the latter in favourable spots to a height of over 5000 feet. Potatoes are found above 6000 feet. In the Etsch valley, or district about Meran and Botzen, red and white wine of excellent quality is produced (in 1884 about 6,500,000 gallons). Of late years the cultivation of fruit has much developed, especially in south Tyrol. Silk is also produced (in 1885 1268 tons of cocoons). Game is still plentiful in the remoter valleys. In every district there are a certain number of licensed hunters, the principal game being red deer, chamois, hares, blackcock, ptarmigan, &c. Mining occupies about one-fifth of the population. At Hall near Innsbruck are important salt works, and at Brixlegg in the same valley copper and lead are smelted. Iron is worked at Fulpmes in the Stubai valley and at Prad in the Vintschgau. Zinc is found at the head of the Passeir valley. In the Middle Ages gold and silver were found in sufficient quantities to make it worth while to extract them. About 4340 square miles of the country are covered with forest, chiefly pine, fir, and larch, which, however, is felled in a recklessly wasteful way. The capital of the county is INNSBRUCK (*q.v.*).

The general average of comfort in Tyrol is high, and the cost of living is very moderate. The peasant and his family are clothed in stuffs spun and woven at home, from the wool and flax produced in their own neighbourhood. The people are for the most part somewhat reserved in manner, but courteous and hospitable. The savage fights which used to be a favourite pastime among the younger men are now almost, or quite, a thing of the past. In some valleys there is a good deal of musical talent; and companies of Tyrolese singers, particularly from the Ziller valley, travel about all over Germany. The zither is a favourite instrument, especially in the southern valleys; in the northern the guitar is more frequent. The religion is almost exclusively Roman Catholic; but in Innsbruck there are some hundreds of Protestants. The priests belong chiefly to the peasant class, and receive their education at Brixen and the university of Innsbruck. This contains about 600 students in the various faculties and possesses a library of some 60,000 volumes. There is a diet, or landtag, with its seat at Innsbruck, consisting of thirty-four representatives of the peasants, thirteen of the citizens, four of the prelates, ten of the nobles, three of the chambers of commerce at Innsbruck, Botzen, and Roveredo, and one of the university of Innsbruck. To the imperial reichsrath Tyrol sends eighteen members. Tyrol is garrisoned by troops recruited exclusively in Tyrol and Vorarlberg, and never, except in time of war, employed outside these provinces. Besides this there are the landwehr and the landsturm or militia.

History.—The country corresponding to modern Tyrol first appears in history when the Rætians were subdued by Drusus and Tiberius. This nation, by some held to have been cognate with the Etruscans, occupied the valleys from the source of the Rhine to that of the Drave. To the north of them were the Vindelici, and to the east the Norici; the former were apparently separated

from them by the ridges north of the Inn, the latter by the watershed between the Etsch and the Drave. Pliny (*N. H.*, iii. 24) gives the names of all the tribes. After their subjection by Rome these races became Romanized and shared the fortunes of the empire. Their position on and about the roads by which the central Alps are most easily crossed laid them especially open to inroads, and before the end of the 3d century the Alemanni had traversed the country. In the course of the next three centuries this people settled in the north-western valleys. But the peopling of the greater part of the province by Teutons was effected by the Baiuvarii, who were by the year 600 established throughout nearly the entire remainder of German Tyrol, some of the Romanized Rhetians probably being left, mixed with a few Alemannic stragglers, in the upper Vintschgau, while the Lombards pressed up from the southward and took possession of the district around Trent. The Alemanni and Baiuvarii, governed immediately by their own dukes, owned a kind of allegiance to the kings of the Franks, and ultimately became in the time of Pippin and Charles incorporated in the Frankish monarchy. The country was then divided for administrative purposes into counties (*comitatus*, *Grafschaften*), under counts, whose rank, at first merely official, in course of time became, with their office, hereditary. The most powerful among them appear to have been those of the Vintschgau, where a fertile soil and a climate less rigorous than that of the northern valleys allowed more development of wealth. In the 12th century the counts of Tirol begin to be conspicuous. This was a small district near Meran, taking its name from the ancient castle of Tirol, known in the later Roman time as Teriolis. These, in the course of the next century, acquired the lordship over nearly all the territory now contained in the province of Tyrol south of the main chain of the Alps, besides the advocacy (*Schirmvogtei*) of the wealthy sees of Brixen and Trent. Meantime the valley of the Inn and those adjoining it had come under the dominion of the counts of Andechs, a Bavarian family, who were also titular counts of Meran. The last of these died without issue in 1248. His wife's sister, Adelaide, married to Meinhard, count of Görz, was left in sole possession of nearly the whole of the province. Their son Meinhard II. (1257-1295) was connected with some of the most powerful houses in Germany; and, being a man of great ability and equal unscrupulousness, he succeeded in acquiring the few outlying portions of territory and castles still belonging to the smaller nobles, and thus consolidated Tyrol within the limits by which it has ever since been bounded. Carinthia and Styria also formed part of his domains; but their connexion with Tyrol has never been other than a personal one. Meinhard II. was succeeded in turn by his sons Otho and Henry. The latter (1310-1335), a weak and extravagant prince, seems to have done much towards organizing the government of the country. His elder daughter Margaret, known in Tyrolese history and legend as *Die Mariltsche*, "the Pocket-mouth," the heiress of his territories, took as her second husband (in 1342) Louis of Brandenburg. Their son Meinhard III., who succeeded to the county on his father's death in 1361, died in 1363. Margaret thereupon made over all her possessions to the house of Hapsburg, and since that time Tyrol has formed part of the hereditary dominions of the archdukes of Austria (see AUSTRIA). The fidelity of the Tyrolese to their counts has for many centuries been proverbial. The Brenner has more than once offered them a secure line of retreat and the mountains a rampart of defence. Maximilian I. (1493-1519) had an especial affection for Tyrol. He conferred on the province its present title of *Die gefürstete Grafschaft*; he profited on more than one occasion by the refuge it afforded; he spent much of his time within it; and at his death he directed that a sumptuous monument to himself should be erected in the Franciscans' church at Innsbruck. Tyrol has more than once been the scene of sharp fighting. In 1499 the men of Graubünden or the Grisons (see SWITZERLAND) invaded the country and defeated the Tyrolese in the neighbourhood of Mals. In 1703 Max Emmanuel, elector of Bavaria, penetrated the upper Inn valley, but was driven back. During the wars of the French Revolution French and Austrian armies met more than once within the limits of the province. By the treaty of Pressburg, 1805, the province was transferred to Bavaria. On the renewal of war between Bonaparte and Austria in 1809 the people rose and expelled the Bavarians, and afterwards, under the leadership of Andrew Hofer, an innkeeper of the Passeier valley, repeatedly defeated the French, Bavarian, and Saxon forces. Innsbruck was more than once taken and retaken; and on 12th August Hofer, after defeating Marshal Lefebvre, was installed in the capital as commandant. But the ill-success of the Austrian arms elsewhere prevented any support from being sent, and by the treaty of Schönbrunn in October the Tyrolese were again given up to their new rulers. Hofer, being captured through treachery, was shot at Mantua, 20th February 1810. On the fall of Bonaparte, Tyrol reverted to the house of Hapsburg.

See A. Jäger, *Die Verfassung Tirols*, Innsbruck, 1881-85; Egger, *Die Tyroler und Vorarlberger*, Innsbruck, 1872-79; Steub, *Drei Sommer in Tirol*, Stuttgart, 1871 (2d ed.).

(A. J. B.)

TYRONE, an inland county of Ireland, in the province

of Ulster, is bounded N. and W. by Donegal, N.E. by Londonderry, E. by Lough Neagh and Armagh, and S. by Monaghan and Fermanagh. Its greatest length from north to south is 46 miles and from east to west 60. The total area in 1881 was 806,658 acres or about 1260 square miles. The surface is for the most part hilly, rising into mountains towards the north and south, but eastwards towards Lough Neagh it declines into a level plain. Running along the north-eastern boundary with Londonderry are the ridges of the Sperrin Mountains (Sawell 2236 feet and Meenard 2064 feet). Farther south there are a range of lower hills and Mullaghearn, to the north of Omagh (1890 feet). South of Clogher a range of hills (1265 feet) forms the boundary between Tyrone and Monaghan. On each side of the Mourne river near Omagh rise the two picturesque hills Bessy Bell and Mary Gray. The Foyle forms a small portion of the western boundary of the county, and receives the Mourne, which flows northward by Omagh and Newtown Stewart. The principal tributaries of the Mourne are the Derg, from Lough Derg, and the Owenkillew, flowing westward from Fir Mountain. The Blackwater, which is navigable by boats to Moy, rises near Five-Mile Town, and forms part of the south-eastern boundary of the county with Monaghan and Armagh. With the exception of Lough Neagh, bounding the county on the east, the lakes are small, also few in number. Lough Fea is picturesquely situated in the north-west, and there are several small lakes near Newtown Stewart. The Ulster Canal runs along the southern boundary of the county from Lough Neagh to Caledon. The substratum of the northern mountains is mica slate interspersed with primary limestone. Yellow sandstone appears in the north-west, in the centre towards Omagh, and in the south-west, where it plunges into Fermanagh. The greater portion of the central area of the county is occupied by Old Red Sandstone. The Tyrone coal-field (6 miles long by 1 to 2 broad) extends between Lough Neagh and Dungannon, all the measures being represented. The coal-field is much broken by faults and has been worked chiefly near the surface, and generally in an unskilful manner; the principal pits are near Dungannon and at Coal Island. The coal is bituminous. There are also indications of copper, iron, and lead.

Agriculture.—The hilly portions of the county are unsuitable for tillage; but in the lower districts the soil is remarkably fertile, and agriculture is generally practised after improved methods, the county in this respect being in advance of most parts of Ireland. The excellent pasturage of the hilly districts affords sustenance to a large number of young cattle. The total number of holdings in 1885 was 27,958, of which 16,469 or nearly two-thirds were each between 5 and 30 acres in extent (8365 between 5 and 15 and 8104 between 15 and 30). Only 43 were above 500 acres; 642 were between 100 and 500 acres, 2378 between 50 and 100, 3937 between 30 and 50, 2573 between 1 and 5, and 1921 did not exceed 1 acre. There were 237,528 acres under crops, including meadow and clover (255,281 acres in 1876), 318,550 acres under grass, 1765 fallow, 9378 woods, 72,071 bog and marsh, 109,539 barren mountain land, and 30,112 water, roads, fences, &c. The area under corn crops decreased between 1876 and 1885 from 115,738 acres to 105,343,—oats from 114,223 acres to 104,040, and wheat from 1166 to 1013. The areas under the other corn crops are very small and fluctuate considerably. The area under green crops between 1876 and 1885 decreased from 64,971 to 59,387 acres,—potatoes from 44,001 to 40,649, turnips from 17,157 to 15,581, mangel wurzel from 750 to 487, and other green crops from 3063 to 2670. Flax (23,901 acres in 1876) covered 16,364 acres in 1885. The area under meadow and clover in 1876 was 50,671, and in 1885 56,434, but there has been no increase since 1878. The number of horses decreased between 1876 and 1885 from 25,038 to 23,185, of mules from 71 to 49, of asses from 1124 to 921, of cattle from 176,841 to 168,072, of sheep from 45,274 to 44,434, and of pigs from 49,012 to 39,530. On the other hand, the number of goats increased from 7950 to 8984, and of poultry from 674,826 to 737,859.

According to the latest landowner's *Return* (1876), the county was divided among 2787 proprietors owning 775,285 acres at a total annual value of £426,224, the average value per acre being nearly

11s. Of the proprietors 1070 owned less than 1 acre each, the total distributed amongst them being 272 acres. The estimated extent of waste land was 4000 acres. The following possessed over 10,000 acres each—duke of Abercorn 47,615 acres, earl of Castle Stuart 32,615, earl of Caledon 29,236, commissioners of church temporalities 28,002, Sir John M. Stewart 27,906, Arthur W. Cole Hamilton 16,683, representatives of Sir William M'Mahon 16,326, Sir William Verner 16,043, earl of Belmore 14,359, Thomas Arthur Hope 13,996, Lord Dorchester 12,608, Michael Smith 10,968, Louisa Elizabeth De Bille 10,455, and Thomas R. Browne 10,125.

Communication.—Besides Lough Neagh and the Ulster Canal, Tyrone has the river Foyle, which is navigable for small craft to a point opposite St Johnstone, and thence by artificial cutting to Strabane, and the Blackwater, which is navigable for boats to Moy. The Great Northern Railway intersects the county by Dungannon, Pomeroy, Omagh, Newtown Stewart, and Strabane.

Manufactures.—The manufacture of linens and coarse woollens (including blankets) is carried on. Brown earthenware, chemicals, whisky, soap, and candles are also made. There are a few breweries and distilleries, and several flour and meal mills. But for the lack of enterprise the coal and iron might aid in the development of a considerable manufacturing industry.

Administration and Population.—The county comprises 8 baronies, 46 parishes, and 2164 townlands. Formerly it returned two members to parliament, the borough of Dungannon also returning one; but in 1885 Dungannon was disfranchised and the county arranged in four divisions—east, mid, north, and south—each returning one member. It is in the north-western circuit, and assizes are held at Omagh and quarter-sessions at Clogher, Dungannon, Omagh, and Strabane. There are fourteen petty sessions districts within the county and portions of four others. The county is in the Belfast military district.

From 312,956 in 1841 the population had decreased by 1861 to 238,500, by 1871 to 215,766, and by 1881 to 197,719 (96,466 males and 101,253 females). In 1881 there were 109,793 Roman Catholics (119,937 in 1871), 44,256 Protestant Episcopalians (49,201 in 1871), 38,564 Presbyterians (42,156 in 1871), 3597 Methodists (3115 in 1871), and 1509 of other denominations (1357 in 1871). The number of persons in the county who could read and write in 1881 was 98,764, who could read only 38,783, the remainder (60,172) being wholly illiterate. Twenty-two persons could speak Irish only and 9796 Irish and English. For the seven years ending 1885 the average number of emigrants annually was 3085. The population of the principal towns in 1881 was—Strabane 4196, Omagh (the county town) 4138, Dungannon 4084, and Cookstown 3870.

History and Antiquities.—Anciently Tyrone was included in the portion of Ulster made "sword-land" by the Scots. It became a principality of one of the sons of Niall of the Nine Hostages, and from his name—Eogain—was called Tir Eogain, gradually altered to Tyrone. From Eogain were descended the O'Neals or O'Neill's and their numerous sept's. The family had their chief seat at Dungannon until the reign of Elizabeth, when it was burned by Hugh O'Neill to prevent it falling into the hands of Lord Mountjoy. The earldom of Tyrone had been conferred on Con Bacagh O'Neill by Henry VIII., but he was driven into the Pale by one of his sons Shan, who with the general consent of the people was then proclaimed chief. From this time he maintained a contest with English authority, but his last remaining forces were completely defeated near the river Foyle in May 1667. During the insurrection of 1641 Charlemont Fort and Dungannon were captured by Sir Phelim O'Neill, and in 1645 the Parliamentary forces under General Munro were signally defeated by Owen Roe O'Neill at Benburb. At the Revolution the county was for a long time in the possession of the forces of James II. Dungannon was the scene of the famous volunteer convention in 1782. Rath's are scattered over every district of the county. There is a large cromlech near Newtown Stewart, another at Tarnlaght near Coagh, and another a mile above Castlederg. At Kilmeillie near Dungannon are two circles of stones. The monastic remains are of comparatively little interest. There are still some ruins of the ancient castle of the O'Neills, near Benburb, and among other ruined old castles mention may be made of those of Newtown Stewart, Dungannon, Strabane, and Ballygawley.

TYRTÆUS, Greek elegiac poet, lived at Sparta about the middle of the 7th century B.C. According to the legend current in later times, he was a native of the Attic deme of Aphidnæ, and was invited to Sparta, on the suggestion of the Delphic oracle, to assist the Spartans in the Second Messenian War. It is difficult, if not impossible, to determine the element of truth in this story. Herodotus at least either did not know, or disbelieved, the tradition, which meets us first in Plato (*Laws*, i. 629A), to the effect that, although Tyrtæus was by birth an Athenian, he had the Spartan citizenship conferred upon

him (see Herod., ix. 35). From Plato down to Pausanias we can trace the gradual growth and expansion of the legend. Ephorus is the first to call Tyrtæus a lame poet; by later generations he is represented as a lame schoolmaster. Basing his inference on the ground that Tyrtæus speaks of himself as a citizen of Sparta (*Fr.* 2 v. 3), Strabo (viii. 4, 10) was inclined to reject the story of his Athenian origin, regarding the elegies in question as spurious. On the whole, perhaps, the conjecture of Busolt (*Gr. Gesch.*, p. 166) comes nearest to the truth: the entire legend may well have been concocted during the 5th century in connexion with the expedition sent to the assistance of Sparta in her struggle with the revolted Helots at Ithome. It is possible, as Busolt suggests, that Tyrtæus was in reality a native of Aphidna in Laconia. However this may be, it is certain from the fragments of his poems that he flourished during the Second Messenian War (*circa* 650 B.C.)—a period of remarkable musical and poetical activity at Sparta (see TERPANDER)—that he not only wrote poetry but took part in the actual service of the field, and that he endeavoured to compose the internal dissensions of Sparta by inspiring the citizens with a patriotic love for their fatherland and its institutions.

We possess in all about twelve fragments of Tyrtæus's poetry, varying in length from one to forty-four lines. They are preserved by Strabo, Lycurgus, Stobæus, and others. We may divide them into two varieties, according to the metre and dialect in which they are composed. The first class consists of elegies in the Ionic dialect, written partly in praise of the Spartan constitution and King Theopompus (*Εὐνομία*), partly to stimulate the Spartan soldiers to deeds of heroism in the field (*Υποθήκαι*—the title is, however, later than Tyrtæus). The interest of the fragments preserved from the *Εὐνομία* is mainly historical: they form our only trustworthy authority for the events of the First Messenian War (*Fr.* 5, 6, 7). The *Υποθήκαι* possess considerable poetic merit, in spite of the occasional monotony of their versification. Addressed to a nation of warriors, they paint in vivid colours the beauty of bravery and the shame of cowardice; there are also lines in them which reveal the soldier as well as the poet, *e.g.*, *Fr.* 10, 31-32. One striking feature is the genuinely Greek feeling for plastic beauty, showing itself in the beautiful picture of the youthful form lying dead upon the battle-field (*Fr.* 10, 27-30, and 12, 23-34; see also Symonds's *Greek Poets*, i. p. 74). The popularity of these elegies in the Spartan army was such that, according to Athenæus (xiv. 630 F), it became the custom for the soldiers to sing them round the camp fires at night, the polemarch rewarding the best singer with a piece of flesh. Of the second class of Tyrtæus's poems, marching songs, written in the anapaestic measure and the Dorian dialect, the remains are too scanty to allow of our pronouncing a judgment on their poetic merit.

See Bergk, *Poetæ Lyrici Græci*, vol. ii. pp. 8-22, Leipsic, 1882. Fragment 10 (*τεθνάμεναι γὰρ καλόν*, &c.) has been translated into English verse by Campbell.

TYTLER. The surname of three Scottish writers, principally on historical subjects.

1. ALEXANDER FRASER TYTLER (1747-1813), Lord Woodhouselee, Scottish judge, was the eldest son of William Tytler (see below), and was born at Edinburgh on 15th October 1747. After passing through the High School, he was sent in 1763 to a school at Kensington taught by Dr Elphinston, the translator of Martial's *Epigrams*. He returned to Edinburgh in 1765, skilled in Latin versification, and with a competent knowledge of Italian, and a taste for drawing and natural history. He was called to the bar in 1770. His first work, a supplement to the *Dictionary of Decisions*, undertaken on the suggestion of

Lord Kames, was published in 1778, and a continuation appeared in 1796. In 1780 Tytler was appointed conjoint professor of universal history in the university of Edinburgh, becoming sole professor in 1786. In 1782 he published *Outlines* of his course of lectures, afterwards extended and republished under the title of *Elements of General History*. The *Elements* has passed through many editions, and has been translated into several European languages as well as into Hindustani. The lectures themselves were published in 1834 in Murray's *Family Library*. In 1790 Tytler was appointed judge-advocate of Scotland, and while holding this office he wrote a *Treatise on the Law of Courts-Martial*. In 1801 he was raised to the bench, taking his seat (1802) in the court of session as Lord Woodhouselee. He died at Edinburgh on 5th January 1813.

Besides the works already mentioned, he was the author of several papers in the *Mirror*, the *Lounger*, and the *Transactions of the Royal Society of Edinburgh*; he also wrote *Life and Writings of Dr John Gregory*; *Essay on the Principles of Translation*, 1790; a dissertation on *Final Causes*, prefixed to his edition of Derham's *Physico-Theology*, 1799; a political pamphlet entitled *Ireland profiting by Example*, 1799; an *Essay on Laura and Petrarch*; and *The Life and Writings of Henry Home, Lord Kames*, 1807.

2. PATRICK FRASER TYTLER (1791-1849), as the son of Lord Woodhouselee and grandson of William Tytler, may be said to have inherited a taste for literary and historical pursuits. He was born at Edinburgh on 30th August 1791, and was educated chiefly at the High School and university, being called to the bar in 1813. His earliest literary effort appears to have been a chapter or two contributed to Alison's *Travels in France* (1815); and his first independent essays were papers in *Blackwood's Magazine*. Inheriting the family talent for music, and with a facility in throwing off humorous little poems and songs, he made several contributions to Thomson's *Select Melodies of Scotland*, 1824. In 1819 he published the *Life of James Crichton of Clunay*, commonly called the *Admirable Crichton*, a second edition appearing in 1823. This was followed by a *Memoir of Sir Thomas Craig of Riccarton*, 1823; an *Essay on the Revival of Greek Literature in Italy*, and a *Life of John Wickliff*, published anonymously, in 1826. The *History of Scotland* was undertaken at the suggestion of Sir Walter Scott, and occupied Tytler for nearly twenty years, in the course of which he removed to London for convenience of research. The first volume appeared in 1828, and the ninth and last in 1843. The original investigations on which the work was founded gave it an authority which no previous history of Scotland possessed, and the clear and graphic style made it interesting and popular. The last few years of his life were spent in physical prostration and mental depression, and he died at Great Malvern on 24th December 1849.

During the progress of his *History* a large amount of other work came from his pen, as the following list shows:—*Lives of Scottish Worthies*, for Murray's *Family Library*, 3 vols., 1831-33; *Historical View of the Progress of Discovery in America*, 1832, and *Life of Sir Walter Raleigh*, 1833, for the *Edinburgh Cabinet Library*; *Life of Henry VIII.*, 1837; *England under the Reigns of Edward VI. and Mary*, from original letters, 2 vols., 1839; article "Scotland" in the seventh edition of the *Encyclopædia Britannica* (afterwards published separately as a school history); *Notes on The Darnley Jewel*, 1843; on the *Portraits of Mary Queen of Scots*, 1845 (privately printed); and *Memoirs of the War carried on in Scotland and Ireland, 1689-91*, by General Mackay, edited in conjunction with Hog and Urquhart, and presented to the Bannatyne and Maitland Clubs in 1833.

3. WILLIAM TYTLER (1711-1792), of Woodhouselee, writer on historical and antiquarian subjects, was the son of Alexander Tytler, writer in Edinburgh, and was born in that city on 12th October 1711. He was educated at the High School and the university, and, having adopted his father's profession, was in 1744 admitted into the society of Writers to the Signet. While successfully practising as a lawyer, he found time to devote attention to historical

investigation. In 1759 he published an *Inquiry, Historical and Critical, into the Evidence against Mary Queen of Scots, and an Examination of the Histories of Dr Robertson and Mr Hume with respect to that Evidence*. This work, which warmly defended the character of the queen, met with great success. Four editions, the later ones considerably enlarged, were published in the author's lifetime; and it was translated into French. In 1783 he published the *Poetical Remains of James the First, King of Scotland*, to which he added a dissertation on the life and writings of the royal author. He wrote an essay on "Scottish Music," which was appended to Arnot's *History of Edinburgh*. His "Dissertation on the Marriage of Queen Mary to the Earl of Bothwell" and "Observations on the Vision, a Poem," appeared in the *Transactions of the Society of Antiquaries of Scotland* (1791-92). A paper in the *Lounger*, on "Defects of Modern Female Education," and an *Account of Fashionable Amusements in Edinburgh in the Seventeenth Century* complete the list of his works. He died at Edinburgh on 12th September 1792.

TYUMEN, a district town of West Siberia, in the government of Tobolsk, is situated at a point where the chief highway from Russia across the Urals touches the first navigable river (the Tura) of Siberia. A railway passing through Ekaterinburg and the principal iron-works on the eastern slopes of the middle Urals connects Tyumen with Perm, the terminus of steamboat traffic on the Kama and Volga. The Tura being a tributary of the Tobol, which joins the Irtysh, a tributary of the Ob, Tyumen has regular steam communication with Omsk and Semipalatinsk by the Irtysh (steamers penetrating as far as Lake Zaisan in Dzungaria); with Tomsk, Barnaul, and Biysk, in the Altai, by the Ob and the Tom; with Irbit—the seat of the great Siberian fair—by the Tura and the Nitsa; and by the Tobol, the Irtysh, and the Ob with the Arctic Ocean and the fisheries of the lower Ob. Tyumen stands also at the western extremity of the Siberian highway which goes via Omsk, Tomsk, and Krasnoyarsk to Irkutsk. In summer the Tura sometimes falls so low that steamers have to stop 90 miles off, passengers and goods being taken thence to Tyumen in lighter vessels. The town is well built, and stands on both banks of the Tura, which is here spanned by a bridge. The portion on the low left bank is inhabited by the poorest class and is often inundated; the best houses are on the high right bank. The streets are unpaved, but the houses (principally wooden) are for the most part inclosed by gardens. The people, who are famed throughout Siberia for their good looks, have always been renowned for their industrial skill. Woollen cloth, linen, belts, and especially boots and gloves, are manufactured to a large amount (70,000 pairs of boots and 300,000 pairs of gloves annually). Tyumen carpets, although made in the simplest way and with the plainest tools, have a wide renown in Russia and Siberia, and recently have appeared in the markets of western Europe as of Oriental origin. All kinds of metal wares are made in small workshops. Sheepskins and various kinds of cloth are extensively manufactured, and the leather prepared at the tanneries (100 in number) is extensively sold all over Siberia, the Kirghiz steppe, and Bokhara. An establishment has recently been opened for the construction of barges, and a paper-mill, the first in Siberia, was opened in 1886. The trade of Tyumen is exceeded only by that of Irkutsk and of Tomsk. In addition to its primary schools Tyumen has a "real" school. The population, which is of a fluctuating character in summer, is differently estimated at 13,000, 14,500, and 18,000.

TZARSKOYE SELO. See TSARSKOYE SELO.

TZETZES, JOANNES, a voluminous Byzantine writer of the 12th century. See GREECE, vol. xi. p. 145 sq.

U

U holds the twenty-first place in our alphabet. The corresponding place in the Greek alphabets was occupied by Y (with some slight variations of form). The form in the Italian alphabets was generally V. These three are only modifications of one original; but they are independent symbols with us, though Y does not represent any sound otherwise unrepresented. It will be most convenient to describe the three forms once for all.

With T we reach the end of the original Phœnician alphabet. The remaining symbols—no fewer than six with us, four in the completed Latin alphabet—are accretions, either modifications of old symbols for greater exactness or old symbols themselves which had fallen out of their proper place and were added again. The first new symbol was needed to represent the important vowel sound *u*. We have already seen that the Greeks employed the Phœnician symbols for the breaths which they did not want as symbols for the vowels which they did want. Thus we should have expected that the Phœnician *vau* would have been used for *u*. But *vau* was already employed for *w*, which was a living sound in early Greek; the form used was F (the so-called digamma), the origin of our F. What then was the origin of the symbol for *u*? In the earliest Greek we find the two forms Y and V, *e.g.*, in inscriptions of Thera. Now the Moabite form of *vau* is Y, which resembles the Y more than F. It is difficult to see why the presumably oldest Phœnician form should appear, not in the sixth place of the Greek alphabet, but at the end, where it must have been an arbitrary addition; and, although the Y form could be derived from F (middle steps are found), it is not easy to get F from Y. We may suppose that the two symbols, F and Y, were obtained by the Greeks from independent Phœnician alphabets, the first being kept by those Greeks who required a symbol for *w*, and did not at first need any special sign to distinguish *u* (which in the earliest Greek times known to us had the value of German *ü*) from *o*; while the others took the form Y to express the modified *u*, and probably never really adopted the F, except as a numeral; it does not appear even in the very old Abu Simbel inscription written by the Ionian mercenaries of Psammitichus. It is noteworthy that in that inscription *both* the forms Y and V appear, whereas in those of Thera and Melos we have sometimes the one sometimes the other, but not both in the same inscription, and a study of the writing leads to the conclusion that the Y was felt to be the true (*i.e.*, the older) form, but that V was used more frequently for the sake of simplicity.

At Rome the single form V denoted both the vowel *u* and also the consonantal *w*. F retained its place as sixth in the alphabet, but with the value of *f*, which was unknown to the Greeks; a peculiar form, C, in which the middle stroke has gone to the bottom, seems to have been affected by its neighbour E; this is found in Etruscan, Umbrian, and Samnite inscriptions; it has, however, the value of *w*; while a curious symbol 8 appears at the end of the Etruscan alphabet, and is also used in the Eugubine tables, with the value of *f*; the origin of this is uncertain. It may be a rounded form of the second symbol in the digraph FB (*i.e.*, FH) by which the sound F is indicated in a very old inscription (see *Rhein. Mus.*, xlii. 317); if this is so, the Latin alphabet has the first member of the digraph, the Etruscan has the second. Next, the symbol Y was added (together with Z) in the 1st century B.C. to represent more exactly, in borrowed words, the sound of Greek upsilon.

Lastly, the form U was differentiated from V. It is the uncial form, and so belongs to the general transition from the pointed to the rounded character which conduced to greater convenience of writing. Examples of it may be seen in the article on PALEOGRAPHY; see the specimen of Latin uncial of the 5th or 6th century (vol. xviii. p. 153), and the half-uncial of the Lindisfarne Gospels, about 700 A.D. (*ibid.*, p. 159). It was clearly a matter of convenience to have separate symbols to represent sounds so distinct as *u* and *v*; but the application of the two symbols seems to have been due to chance rather than design. The form V remained in use at the beginning of words, whereas *u*, which was the uncial and cursive form, naturally was used rather in the middle; by degrees the initial form was appropriated to consonants,—perhaps, as Dr Taylor suggests (*Alphabet*, ii. 189), because the consonant is commoner at the beginning of words, or for some other reason, while the medial form was connected with vowels.

The sound which U denotes is produced by “rounding” the lips to the furthest extent consistent with a clear vowel-sound, and by raising the back of the tongue higher than for any other rounded sound. It has two varieties (like all other vowels) according as the position of the tongue is more or less tense, producing thereby a narrower or a wider aperture for the voice to pass through; whence the sounds are technically called “narrow” and “wide” respectively. The narrow sound is heard in English only when the vowel is long, as in “book,” “rule,” but in northern English (Scotch) “book” may be heard short. The wide sound is heard in “full,” “good.” The digraph *oo* is commonly used for the *u* sound, and attests the fact that the original sound of *ō* has frequently passed into *ū*, as in “good,” “food,” &c., written “gode,” “fode” in Middle English; sometimes, however, the *oo* has come by analogy into words where *ū* is the original sound, as in “room,” M.E. “roum,” O.E. “rūm.” Original *ū* has commonly passed into the *au* sound, spelt in English *ou* or *ow*, as in “how,” “house,” “mouse,” “bower,” for O.E. “hū,” “hūs,” “mūs,” “būr.” According to Mr A. J. Ellis, words derived from the French had in Chaucer’s time the sound of French *u*; and Sir John Cheke’s statement “cum duke, tute, lute, rebuke, duk, tuk, lut, pebuk dicimus, Græcum *u* sonaremus,” seems strong for the same practice in the 16th century. In the 17th century the modern pronunciation of *u* as *i* in “muse,” “duke,” “mute,” “pure” had come in. Hence also we may explain the substitution of *u* for *y* in some genuine English words, as “busy” (orig. *bysig*). At the same time begins the corruption of *u* to the (so-called) *ʊ* sound in “but,” “shut,” &c.; this is not a *u* sound at all, but the neutral vowel as heard indifferently in “but,” “sun,” “son,” “blood”; it is often confounded by writers with the true *ʊ* heard in “pull” and in the northern pronunciation of “but,” “shut.” For the history of the German “modified” *u* (spelt *ü*, but originally *ue*) see under Y.

UBEDA, a town of Spain, head of an administrative subdivision in the province of Jaen, stands on a gentle slope about 5 miles from the right bank of the Guadalquivir, and about 22 miles to the east of the Menjibar station on the railway from Madrid to Cordova. Under the Moorish rule it was a place of considerable consequence, its population being said to have at one time numbered 70,000. Some portions of the old walls, with towers and gates, still remain, but none of the public buildings are of great age, the oldest church, that of San

Salvador, dating from 1540–56. The population within the municipal boundaries in 1877 was 18,149.

UDAIPUR [OODYPORE], or MEWAR, a native state in Rajputana, India, with an area of 12,670 square miles. It extends from 23° 49' to 25° 58' N. lat., and from 73° 7' to 75° 52' E. long., and is bounded on the N. by the British territory of Ajmere; on the E. by the native states of Bundi, Gwalior, Tonk, and Partábgarh; on the S. by Banswára, Dungarpur, and Mahi Kántha; and on the W. by the Aravalli Mountains, separating it from Marwar and Sirohi. The greater part of the country is level plain. A section of the Aravalli Mountains extends over the south-western and southern portions, and is rich in minerals, but the mines have been long closed. The general inclination of the country is from south-west to north-east, the Banas and its numerous feeders flowing from the base of the Aravalli range. There are many lakes and tanks in the state, the finest of which is the Dhebar or Jaisamand, with an area of nearly 21 square miles; it is considered to be the largest sheet of artificial water in the world. There are only two metal roads in the state; the Nimach State Railway passes through the north-eastern part.

In 1881 the population, exclusive of 51,076 Bhils, was 1,443,144 (males 772,685, females 670,459); Hindus numbered 1,321,521, Mohammedans 43,322, Jains 78,171, and Christians 130. The only town with over 10,000 inhabitants is Udaipur, the capital (88,214). This city is picturesquely situated on a lake 2000 feet above sea-level, and faces wooded hills. It contains the royal palace, which is a noble pile of granite and marble, built on the crest of a rocky ridge overlooking the lake, city, and valley. There are no manufactures of any importance in the state, and the crops as a rule only suffice for local wants. The principal imports are salt, piece goods, groceries, metals, medicines, sugar, ivory, and tobacco; and the exports are mostly confined to turmeric, gúr, cotton, indigo, til, opium, and cattle. The total income of Udaipur in 1885–86 was £259,624. The state was taken under the protection of the British Government in 1817, and it pays an annual tribute of £20,000. The family of the raja of Udaipur ranks highest in dignity among the Rajput chiefs of India.

UDAL (Danish *odel*) is a kind of right still existing in Orkney and Shetland, and supposed to be a relic of the old allodial mode of landholding existing antecedently to the growth of feudalism in Scotland. The udal tenant holds without charter by uninterrupted possession on payment to the crown, the kirk, or a grantee from the crown of a tribute called scat (Danish *skat*), or without such payment, the latter right being more strictly the udal right. Udal lands descend to all the children equally. They are convertible into feus at the option of the udallers.

UDALL, NICHOLAS (b. 1505–d. 1561), author of the earliest extant regular English comedy. Udall was a typical man of the Renaissance in England, a schoolmaster by profession, a classical scholar, a translator of Terence and Erasmus, and a writer of pageants and interludes. He was high in favour at court, wrote verses for the city pageant exhibited at Anne Boleyn's coronation in 1533, and was honoured by Mary in 1554 as one that had "heretofore showed and mindeth hereafter to show his diligence in setting forth of dialogues and interludes before us for our regal disport and recreation." The severity of his discipline at Eton, where he was headmaster, has been immortalized by the quaint lines of one of his pupils, Thomas Tusser. The exact history of the production of his comedy *Ralph Royster Doyster* is not known. A printed copy wanting the title-page came to light in 1818, and we know that it was licensed to be printed in 1566. It is a distinct advance in construction on the Merry Interludes of John Heywood, but it is not a comedy in the strict English sense, being, like the interludes, essentially farcical

in motive, character, and incident. Although an imitation of the Latin comedy, it is far from being a servile imitation, and abounds in fresh fun and cleverness. It has been twice reprinted,—by the Shakespeare Society (with a memoir by Mr Cooper) and in Arber's Reprints.

UDINE, a town of Italy, in the province of Udine, in a wide plain near the foot of the Carnic Alps, on the Roja, 84 miles by rail north-east from Venice and 49 miles north-west from Trieste. It is enclosed by an imposing wall of considerable antiquity, some 4 or 5 miles in circumference, and fortified with towers. In the centre, on an eminence, stands the old castle, at one time the residence of the patriarchs of Aquileia, and now used as a prison. Grouped around this is the old part of the town, with narrow crooked streets, some of which are lined with arcades. The cathedral, which is a Romanesque building with fine pillars, and an hexagonal tower bearing 14th-century sculptures, contains some interesting examples of native art (by Giovanni Martini da Udine and others). The church of S. Maria della Purità has frescos by Tiepolo. On the principal square stands the town-hall, built in 1457 in the Venetian-Gothic style, and skilfully restored since a fire in 1876; opposite is a clock tower resembling that of the Piazza di San Marco at Venice. The archiepiscopal palace and Museo Civico, as well as the municipal buildings, have some valuable paintings. Several of the palaces of the nobility have striking architectural features, and the town is adorned by many beautiful public walks. The leading industry of Udine is silk-spinning, but it also possesses manufactures of linen, cotton, hats, and paper, tanneries, and sugar refineries, and has a considerable trade. The population in 1881 was 23,254.

Udine is the *Vedimum* of Pliny: it was then a municipium, but quite an inconsiderable place compared with Forum Julii (Cividale) 11 miles to the east, or Aquileia 22 miles to south-south-east. In the Middle Ages it became a flourishing and populous city; in 1238 the patriarch Berthold made it the capital of FRIULI (*q.v.*), and in 1420 it became Venetian.

UEBERWEG, FRIEDRICH (1826–1871), best known by his *History of Philosophy*, was born on the 22d January 1826 at Leichlingen, in Rhenish Prussia, where his father was Lutheran pastor. His mother, left early a widow, devoted her scanty means to the education of her only son. Ueberweg passed through the gymnasium at Elberfeld, and studied at the universities of Göttingen and Berlin. In 1852 he qualified himself at Bonn as privat-docent in philosophy. His *System of Logic*, published in 1857 (English translation 1871), and his essay *On the Authenticity and the Order of the Platonic Writings*, crowned by the Imperial Academy of Vienna (published 1861), contributed to draw attention to him as at once a scholar and a thinker. In 1862 he was called to Königsberg as extraordinary professor, and in 1867 he was advanced to the ordinary grade. He married in 1863, and on the 9th June 1871 he died prematurely.

The chief work of his later years was his compendious *History of Philosophy*, which is unmatched for fulness of information combined with conciseness, accuracy, and impartiality of treatment. The first part appeared in 1862. An English translation, in two volumes, was published in 1872, and has gone through several editions. Ueberweg translated, in 1869, Berkeley's *Principles of Human Knowledge*, with notes, for Kirchmann's *Philosophische Bibliothek*. In philosophy Ueberweg was strongly opposed to the subjectivistic tendency of the Kantian system, maintaining in particular the objectivity of space and time, which involved him in a somewhat violent controversy with several opponents. His own mode of thought he preferred to describe as an ideal realism, which refused to reduce reality to thought, but asserted a parallelism between the forms of existence and the forms of knowledge. Beneke and Schleiermacher seem to have exercised most influence upon the development of his thought. A short memoir, by his friend F. A. Lange (author of the *History of Materialism*), gives some account of what may be called personal opinions in philosophy and theology, which did not find expression in Ueberweg's published writings.

¹ The date of Udall's death is sometimes erroneously given as 1564, in which year his play of *Ezekias* was performed at Cambridge before Queen Elizabeth. He was buried at St Margaret's, Westminster, on 23d December 1566 (see memoir in Cooper's edition of *Royster Doyster*).

UFA, a government of south-eastern Russia, on the western slope of the Urals, has Vyatka and Perm on the N., Orenburg on the E. and S., Samara and Kazan on the W., and comprises an area of 47,112 square miles. In virtue alike of its physical characters and of its population, which belongs chiefly to the Ural-Altaic stock, it forms an intermediate link between Europe and Asia, and it was only recently separated from the government of Orenburg, which is now limited to the eastern slopes of the Urals. Several craggy and densely wooded ridges, running from south-west to north-east parallel to the main chain of the southern Urals, occupy its eastern part. They are separated by broad and long longitudinal valleys, and rise to altitudes of from 2500 to 3500 feet above the sea; their highest peaks—Iremel (5040 feet), Nurgush, Urenga, and Taganai (3950 feet)—are above the limits of tree-vegetation, but in no case reach those of perpetual snow. The high longitudinal valleys of the Urals are the seat of an important mining industry. Southward Ufa extends over the slopes of the Obshchiy Syrt plateau, the angular space between the latter and the Urals being occupied by elevated plains (from 1000 to 1500 feet), deeply grooved by the river valleys and sometimes described as the "Ufa plateau." It slopes gently towards the depression of the Kama; and its undulating surface, especially its broad valleys (500 to 600 feet above the sea), covered as they are with a fertile soil, are being rapidly colonized by Russian settlers. Towards the Kama the fertility of the soil increases, and the black-earth regions of Menzelinsk and Birsik may be described as granaries for that part of Russia.

The geological structure of Ufa is very varied. The main ridge of the Urals consists of gneisses and various crystalline slates resting upon granites and syenites; next comes a broad strip of limestones and sandstones, the fossil fauna of which is intermediate in its lowest parts between the Upper Silurian and the Lower Devonian. These form the highest ridges of Ufa. Farther west the Devonian deposits are followed by Lower and Upper Carboniferous and "Artinsk schists," which, together with Permian deposits, cover western Ufa. Quaternary deposits are extensively developed in all the valleys, most of which were occupied by lakes during the Lacustrine period. Ufa has not the mineral resources of Perm; only traces of gold have been found in its valleys, and silver ores are absent; but its wealth in iron (Devonian) and copper (Permian) seems likely to have great mining importance in the future. The district of Zlatoust is celebrated for its granite, epidote, nephrite, and a variety of decorative stones and minerals. Coal is spread over a wide area, but only in layers too thin to make working remunerative. Fire-clay, kaolin, and sandstone for making grindstones are obtained to some extent; naphtha, sulphur, and saltpetre have been observed in several places.

Ufa belongs almost entirely to the drainage area of the Byelaya, a great tributary of the Kama, which rises in Orenburg, flows south and west till it pierces a mountain chain at Bugutchan, and then runs north and north-west, watering the high plains and receiving a number of important tributaries, among which the Sim, the Tanyp, and the Ufa are also navigable. The banks of the Byelaya are thickly peopled, and it is an important channel for trade; but it sometimes reaches so low an ebb in summer that steamers cannot proceed beyond Birsik. The Kama flows for 120 miles along the western border of the government. Marshes lie along its course, so that its banks are but thinly inhabited. Forests cover nearly half the area, but the plains on the left of the Byelaya are comparatively thinly wooded. The climate of Ufa is very continental. The average temperature at Ufa is 37° F., and the winter is extremely cold (January 5°-5 F., July 68° F.); at the Zlatoust observatory (1340 feet) the average temperature is only 32°-2 (January 2°; July 61°-8). Even in the hilly tracts of Zlatoust the annual rainfall is only 19 inches. The rivers are frozen 158 days at Ufa, and 202 about Zlatoust.

The population of Ufa is now rapidly increasing (1,793,260 in 1882, as against 1,291,020 in 1865). Only one-third of the whole is Russian, the remainder being chiefly Bashkirs (50 per cent., including Mescheriaks and Tepters), Tartars (8·4 per cent.), Tchermishes, Tchuvashes, Mordvinians, and Votiaks. In the south the Bashkirs, Tartars, and other Ural-Altaians constitute two-thirds of the population. Among the Russians two distinct elements must be distinguished,—some 100,000 peasants, who formerly were mining serfs, and now support themselves chiefly by work in or for the mines, and nearly 620,000 agriculturists, for the most part more recent immigrants. The latter carry on agriculture on an extensive

scale, and export large quantities of corn. The Bashkirs are chiefly cattle-breeders, but of late they have been driven more and more to tillage, owing to the appropriation by speculators of their extensive pasture-lands. Bee-keeping is largely carried on, and hunting is still an important source of income to the Bashkirs. In the north-east the trade in timber and the manufacture of various wooden wares are largely engaged in by the peasantry. The mining industry is advancing, notwithstanding many obstacles (see vol. xxi. p. 85); the iron-works of Zlatoust especially have a wide reputation. Flour-mills, distilleries, and tanneries come next in importance. The exports of corn, linseed, timber, wooden wares, metals, tallow, hides, and cattle are considerable, and trade is active, especially at the fairs of Menzelinsk, Ufa, and Zlatoust.

There are six administrative districts, the chief towns of which (with populations in 1884) are—Ufa (25,660), Belebei (4200), Birsik (8000), Menzelinsk (6100), Sterlitamak (8940), and Zlatoust (18,990). The leading places Tchebny and Berezovka on the Kama, and several iron and copper works (Satsinsk, Yurezan, Katav-Ivanovsk, about 6000 inhabitants each) ought also to be mentioned.

UFA, capital of the above government, is situated at the confluence of the Ufa with the Byelaya, on high crags intersected by ravines, which are covered with gardens and orchards. The better part of the town contains a few stone buildings connected with the administration, two cathedrals, and a few churches; the remainder is a scattered aggregation of small wooden houses. There are two classical gymnasiums for boys and girls, a theological seminary, and several lower schools. The town has a few good hospitals. The manufactures are insignificant in Ufa itself, but there are several iron and copper works of importance within the district. Owing to the fertility of the neighbouring regions, and the position of the town at the junction of two important rivers, the Ufa merchants carry on a brisk export trade. The population has rapidly increased of late, reaching 25,660 in 1884.

Ufa was founded in 1574, when a fort was built on the Byelaya, three other forts being erected about the same time at Birsik, Menzelinsk, and Berezovka, to connect Ufa with the Russian settlements on the Kama. The wooden kreml of Ufa, protected by wooden towers and an outer earthen wall, had to sustain the attacks of the revolted Bashkirs and Russian serfs in 1662 and at later dates; and in 1773 Tchika, one of the chiefs of the Pugatcheff revolt, besieged it for four months.

UGANDA, a country of eastern Central Africa, to the north-west of the Victoria Nyanza. It has an area of about 34,000 square miles, extending from 1° N. lat. to the Kitangule river, and from 31° E. long. to the Nile. The country bordering the lake and to the north-west is mountainous, the mountains being arranged in low parallel chains. The hills, covered with splendid timber and abundant underwood, rise to a height of 400 feet above their valleys, through which sluggish streams flow to the lake. Farther north the country becomes a plain, and the eastern portion of Uganda, between Rubaga and the Nile, consists of undulating country, varied by deep narrow valleys. The geological formation of the country is volcanic or metamorphic; two or three feet of rich black alluvial soil form the upper strata, covering a bed of red sandy clay, often 30 feet thick. In some places porcelain earth is found, as well as large masses of mica. Ironstone is present in considerable quantities, but as yet no other metals have been discovered. The climate is mild, and the temperature remarkably uniform throughout the year; the thermometric range is from 50° to 90° F.; but the mean annual variation is only 20°. The annual rainfall is 50 inches, the greatest amount of rain occurring in March, April, May, and September, October, and November, when rain falls nearly every day, thunderstorms being frequent.

The population of Uganda is about five millions. The men are tall and well-built, and have good features and dark chocolate-coloured skin, with woolly hair. The women in their youth are good-looking. The country is divided into three provinces—Uddu in the south, Singo in the west, and Changwe in the east, to which must be added about 400 islands in the lake. The government of the country is feudal, the king being nominally supreme. Succession to the throne is hereditary, but the successor is usually a minor

chosen by three hereditary chiefs, who with the young king's mother carry on the government until he is of age. The reigning family in Uganda is descended from the Wahuma tribe; the late king Mtesa professed to trace back his descent to Kintu (or Ham), the founder of the dynasty. The country is ruled by the king, three hereditary chiefs, and a council of minor chiefs,—two hereditary chiefs and a certain proportion of the others being continually in residence at Rubaga, the capital of the country. The laws are strict, and the administration of justice is conducted in an orderly manner. There is no real taxation, but the people are compelled to render feudal service to all their superiors. The Waganda may be divided into four classes, the lowest class being the slave population, consisting of prisoners taken in war and their descendants; next come the "bachopi" or peasants, who form the mass of the population; the third class are the "batongoli," or chiefs, who are recruited from the bachopi, but whose honours are not hereditary; they receive their rank for distinguished bravery in the field or for services rendered to the state, and they are the governors of the villages. The highest class is that of the "bakungu," a superior grade of chiefs, all belonging to the "luchiko" or state council, and being governors of large districts of land. The three great hereditary chiefs belong to this class, and they are supreme governors of the three great districts into which Uganda is divided. The Waganda are very warlike; all adult males are compelled to serve in the army when required, and the military organization, having its headquarters at the capital, ramifies throughout the whole land. Game is very plentiful: elephants, buffaloes, zebras, rhinoceroses, wild boars, twelve species of antelopes, lions, leopards, jackals, foxes, hyenas, hares, chimpanzees, and several species of monkeys inhabit the forest. Snakes are numerous; hippopotami, crocodiles, and otters abound in the lake and in the Nile, as also many water-rats. The principal birds are parrots, guinea-fowl, owls, vultures, adjutants, goatsuckers, kites, eagles, ducks, geese, storks, cranes, herons, gulls, scarlet flamingos, darters, the sacred and glossy ibis, and brilliantly coloured honey-birds. The principal insects are mosquitos, fleas, locusts, white and driver ants, and butterflies of many species. The domestic animals are cows, goats, and a few sheep and dogs. The Waganda live chiefly upon a vegetable diet, the banana forming the staple food; it grows everywhere, and requires little or no cultivation. The sweet potato is the chief vegetable cultivated, but coffee, sugar-cane, cassava, maize, sesame, millet, tullabone, several species of beans, and two or three kinds of pumpkins are grown to a small extent. The principal fruits are the mpafu and a species of amomum. Strangers have introduced wheat, rice, guavas, papaws, pomegranates, tomatoes, onions, and radishes. Wine is made from the banana tree, and is a staple drink. Butter and cheese are also made. A good deal of manufacture is carried on, for the people are ingenious and clever workmen, and their work is tasteful, neat, and exact. Two kinds of pottery, a coarse and a fine variety, are manufactured in considerable quantities. The basket work is extremely good, and the metal work far superior to any seen among the neighbouring tribes. The manufacture of bark-cloths, in which most of the people are clothed, is very extensively carried on, and their wood-work and boat-building are of very superior quality. Tanning, dyeing, and bead-work employ numbers of the people. There is not very much home trade in Uganda; it is limited to the barter of native manufactures. Several times a year caravans arrive from Zanzibar, bringing calico, guns, powder, files, knives, &c. The standard value of any article is reckoned by 100 cowries or an arm's length of calico and beads; hoes, salt, and fish are also employed as mediums of exchange. The language spoken in Uganda belongs to the great Bantu family, and is very rich in words. It has ten classes of nouns, the noun being the most important part of speech. Grammatical inflexions are formed by prefixes; the inflexions of verbs, adjectives, and pronouns vary according to the class of the governing noun. Adjectives agree with the substantive in number and case, and always follow the noun. There are personal, possessive, relative, demonstrative, and interrogative pronouns, and several forms of verbs. The Waganda are very good arithmeticians. The root of all multiples is ten; tallies are used as aids to the memory. The people are very musical; their voices are clear and melodious, and of considerable range. They have a great variety of tunes,—orchestral, dance, and vocal music having distinct characteristics. Their musical instruments consist of harmonicons, rattles, drums, horns, whistles, flutes, and harps. The Waganda have no images or outward symbols of their gods; and they think that the world is ruled by spirits or demons, to whom Katonga, the great creator, has deputed his power. They worship Mukasa, the god of the lake; Naduala, the god of small-pox; Chiwuka and Nenda, the gods of war; and several of the former monarchs of Uganda, who are believed to be demi-gods. A thunder spirit is also invoked. The gods of war are supposed to inhabit certain trees, and offerings are made to them before entering the war-path; like offerings are also made to the god of the lake before commencing a voyage upon its waters. The Waganda are courteous, cleanly, given to hospitality, but drunken, and to a certain extent indolent. Their standard of

morality, even judged by that of the surrounding tribes, is not high. Human life is little respected; they are untruthful and indecent. Unless moved by passion, they are not cruel; passionate, they are not revengeful. Children are well treated, as are the aged men. On account of the extensive prevalence of polygamy, women occupy a somewhat low social grade.

Uganda was first visited by Speke and Grant in 1860, and the country has since been visited by numerous Europeans, chiefly missionaries. The Church Missionary Society and the Roman Catholics have mission stations in the country. In 1886 some forty of their converts were burnt at the stake, and in the same year Bishop Hannington was murdered on the borders of the country by the orders of King Mwanga.

Felkin, in *Proc. Roy. Soc. Ed.*, vol. xiii., and an *Outline Grammar of the Luganda Language*, by C. T. Wilson.

UGLITCH, a district town of Russia, in the government of Yaroslavl, is situated on the upper Volga, principally on its right bank, 67 miles to the west of the capital of the province. Its historical remains are mostly associated with the prince Dmitri (see vol. xxi. p. 93). The wooden house he occupied, a church of St Demetrius "on the Blood" erected at the spot where he was killed, and a kiosk on the site of the convent where his mother was forcibly consecrated a nun,—all commemorate this chapter in the history of the rule of the boiars at Moscow at the beginning of the 17th century. An old cathedral, erected in the 13th century but subsequently restored, and containing the grave of Prince Roman, recalls a still earlier period of municipal independence. Uglitch has now become a commercial and industrial city with 11,930 inhabitants (1883), and has an important trade, being one of the chief loading places on the upper Volga. Its industries comprise the sewing of sacks for corn and flour (about one million every year) and the knitting of woollen socks; and it has a paper-mill, distilleries, copper works, and linen factories. Corn, paper, sausages (with which the name of Uglitch has long been associated), candles, &c., are shipped at the town.

Uglitch is one of the oldest towns of Russia; its local annals go as far as back as the 9th century. Until the 14th century it maintained its independence as a separate principality, which extended over eastern Tver, and elected its own princes. In 1329 the sons of Prince Roman the Saint renounced their independence in favour of Moscow, and fifty years later the Uglitch princes finally sold their rights to the great prince of Moscow. The Tartars plundered the town during their invasions of 1237, 1293, and 1408, as also did the Lithuanians at a later date.

UGRIANS. See FINLAND, vol. ix. p. 219.

UHLAND, JOHANN LUDWIG (1787–1862), German poet, was born at Tübingen, on April 26, 1787. He studied at the university of his native place, taking jurisprudence as his special subject, but also devoting much time to literature. Having graduated as a doctor of laws in 1810, he went for some months to Paris; and from 1812 to 1814 he worked at his profession in Stuttgart, in the bureau of the minister of justice. He had begun his career as a poet in 1807 and 1808 by contributing ballads and lyrics to Seckendorf's *Musenatmanach*; and in 1812 and 1813 he wrote poems for the *Poetischer Almanach* and for the *Deutscher Dichtervald*. In 1815 he collected his poems in a volume entitled *Gedichte*, which almost immediately secured a wide circle of readers, and gives him his place in German literature. To every new edition he added some fresh poems; and the sixtieth edition, published in 1875, included a number of pieces found among his papers. He wrote two dramatic works—*Ernst, Herzog von Schwaben* and *Ludwig der Baier*—the former published in 1817, the latter in 1819. These, however, are unimportant in comparison with his *Gedichte*. In some respects Uhland must be classed with the writers of the romantic school, for, like them, he found in the Middle Ages the subjects which appealed most strongly to his imagination. But his style has a precision, suppleness, and grace which sharply dis-

tinguish his most characteristic writings from those of the romantic poets. His best lyrics have the charm which belongs to the unaffected expression of delicate sentiment; and in almost all his ballads he displays a remarkable power of giving picturesque form to his conceptions of character. He was a man of pure and noble impulse, and it was in presenting scenes which awaken love, or admiration, or pity that he did the fullest justice to his powers. Uhland's poetic sympathy with some characteristics of the age of chivalry did not prevent him from sharing the best aspirations of his own time. He wrote manly poems in defence of freedom, and in the states assembly of Würtemberg he played a distinguished part as one of the most vigorous and consistent of the liberal members. In 1829 he was made a professor, at Tübingen university, of German literature and the German language, but he resigned this appointment in 1833, when it was found to be incompatible with his political duties. In 1848 he became a member of the Frankfort parliament, in which he sat as one of the most respected members of the liberal party.

Uhland was not only a poet and politician; he was also an ardent student of the history of literature. In 1812 he published an interesting essay on *Das altfranzösische Epos*; and ten years afterwards this was followed by an admirable work on Walther von der Vogelweide. He was also the author of an elaborate study of *Der Mythos von Thór nach nordischen Quellen* (1836), and he formed a valuable collection of *Alte hoch- und niederdeutsche Volkslieder*, which appeared in 1844-45. He died on November 13, 1862. After his death his prose works were reprinted, with some additions, under the general title *Uhland's Schriften zur Geschichte der Dichtung und Sage* (1865-73), and an edition of his poems and dramas, in three volumes, was issued in 1863.

See Liebert, *Ludwig Uhland, eine Skizze* (1863); Mayer, *Ludwig Uhland, seine Freunde und Zeitgenossen* (1867); and *Ludwig Uhland's Leben, aus dessen Nachlass und aus eigener Erfahrung zusammengestellt von seiner Witwe* (1874).

UJJI, a town in eastern Central Africa, of considerable importance, also known by the name of KAVELE, is situated on the eastern shores of Lake Tanganyika, in 4° 55' S. lat. and 30° 5' E. long. It is the chief town on that lake, and is the centre of a brisk trade in ivory. Formerly it was a great slave-market. The town is of a straggling character, Arab houses of sun-dried bricks being mingled with native huts. The population, which fluctuates considerably, is very mixed, being composed of Arabs and the representatives of numerous Central African tribes. Ujji has been visited by various European travellers, who have made it their headquarters, and it was here that Stanley found Livingstone, on October 28, 1871. Opinions vary as to the salubrity of its climate, but the balance of testimony appears to prove that during the greater part of the year it is very unhealthy.

UJJAIN, or Oojein, a town in the native state of Gwalior, central India, situated on the right bank of the Sipra, in 23° 11' 10" N. lat. and 75° 51' 45" E. long., 1698 feet above sea-level. In ancient times Ujjain was the great and famous capital of Málwá, one of the seven sacred cities of the Hindus, and the spot which marked the first meridian of Hindu geographers. Though much decayed, it is still a large and populous city, with considerable commerce. The modern city is surrounded on all sides by an almost uninterrupted belt of groves and gardens. In 1881 the population of the town numbered 32,932. Its trade consists chiefly in the export of opium and the import of European goods, especially cotton fabrics.

UKRAINE ("frontier"), the name formerly given to a district of European Russia, now comprising the governments of KHARKOFF, KIEFF, PODOLIA, and POLTAVA (q.v.).

ULCER. See SURGERY, vol. xxii. p. 683.

ULFILAS (311-381), the apostle of Christianity to the Gothic race, and, through his translation of the Scriptures into Gothic, the father of Teutonic literature, was born among the Goths of the trans-Danubian provinces in the year 311.¹ There is a tradition that his ancestors were Christian captives from Sadagolthina in Cappadocia, who had been carried off to the lands beyond the Danube in the Gothic raid of 267; but the evidence on which this rests is inadequate. An authoritative record of the outlines of his life has only been discovered within the last fifty years, in a writing of Auxentius, his pupil and companion.

At an early age Ulfilas was sent, either as an envoy or as a hostage for his tribe, to Constantinople, probably on the occasion of the treaty arranged in 332. During the preceding century Christianity had been planted sporadically among the Goths beyond the Danube, through the agency in part of Christian captives, many of whom belonged to the order of clergy, and in part of merchants and traders. Ulfilas may therefore have been a convert to Christianity when he reached Constantinople. But it was here probably that he came into contact with the Arian doctrines which gave the form to his later teaching, and here that he acquired that command over the Greek and Latin tongues which equipped him for his labours as a translator. For some time before 341 he worked as a "lector" or reader of the Scriptures, probably among his own countrymen in Constantinople, or among those attached as *federati* to the imperial armies in Asia Minor. From this work he was called to return as missionary bishop to his own country, being ordained by Eusebius of Nicomedia and "the bishops who were with him" in 341. This ordination of Ulfilas as missionary bishop by the chiefs of the semi-Arian party is at once an indication of their determination to extend their influence by active missionary enterprise and evidence that Ulfilas was now, if he had not been before, a declared adherent of the Arian or semi-Arian party. He was now thirty years of age, and his work as "bishop among the Goths" covered the remaining forty years of his life. For seven of these years he wrought among the Visigoths beyond the Danube, till the success which attended his labours, and the growing numbers of his flock, drew down the persecution of the still pagan chief of the tribe. This "sacrilegus iudex" has been identified with Athanaric, a later persecutor, probably without sufficient ground. The persecution was so severe that, to save his flock from extinction or dispersion, Ulfilas decided to withdraw both himself and his people from its range. With the consent of the emperor Constantius, he led them across the Danube, "a great body of the faithful," and settled in Mœsia at the foot of the range of Hæmus, and near the site of the modern Tirnova (348). Here they developed into a peace-loving pastoral people.

The life of Ulfilas during the following thirty-three years is marked only by one recorded incident, his visit to Constantinople in 360, to attend the council convened by the Arian or Homoian party. His work and influence were not, however, confined to his own immediate flock, but radiated by means of his writings (homilies and treatises), and through the disciples he despatched as missionaries, among all the tribes of the Gothic stock beyond the Danube. By this time probably he had made some progress with his version of the Scriptures, and copies of parts of it would begin to circulate. Thus the church beyond the Danube, which had not been extinguished on Ulfilas's withdrawal, began to grow once more in numbers and importance, and once more had to undergo the fires of persecution. Catholic missionaries had not been wanting in the meanwhile, and in the indiscriminate persecution by

¹ Krafft gives 313 as the date, Waitz 318.

Athanasius between 370 and 375 Catholics and Arians stood and fell side by side. The religious quarrel either accentuated, or was accentuated by, political differences, and the rival chiefs, Athanasius and Frithigern, appeared as champions of Paganism and Christianity respectively. Then followed the negotiations with the emperor Valens, the general adhesion of the Visigoths under Frithigern to Arian Christianity, the crossing of the Danube by himself and a host of his followers, and the troubles which culminated in the battle of Adrianople and the death of Valens (378). The part played by Ulphilas in these troublesome times cannot be ascertained with certainty. It may have been he who, as a "presbyter Christiani ritus" conducted negotiations with Valens before the battle of Adrianople; but that he headed a previous embassy asking for leave for the Visigoths to settle on Roman soil, and that he then, for political motives, professed himself a convert to the Arian creed, favoured by the emperor, and drew with him the whole body of his countrymen,—these and other similar stories of the orthodox church historians appear to be without foundation. The death of Valens, followed by the succession and the early conversion to Catholicism of Theodosius, dealt a fatal blow to the Arian party within the empire. Ulphilas lived long enough to see what the end must be. Hardships as well as years must have combined to make him an old man, when in 381 he was sent for to Constantinople. The emperor had summoned him, for what purpose cannot be clearly ascertained. A split seems to have taken place among the Arians at Constantinople. Party riots were too familiar there, and a fierce dispute over a theological dogma, however abstruse, placed the peace of the city, if not the security of the palace, in jeopardy. Ulphilas was summoned to meet the innovators, and either by argument or by influence to induce them to surrender the opinion which caused the dispute. His pupil Auxentius describes how, "in the name of God," he set out upon his way, hoping to prevent the teaching of these new heretics from reaching "the churches of Christ by Christ committed to his charge." No sooner had he reached Constantinople than he fell sick, "having pondered much about the council," and before he had put his hand to the task which had brought him he died, probably in January 381. A few days later there died, also in Constantinople, his old enemy and persecutor, Athanasius.

The Arianism of Ulphilas was a fact of pregnant consequence for his people, and indirectly for the empire. It had been his lifelong faith, as we learn from the opening words of his own testament—"Ego Ulphilas semper sic credidi." If, as seems probable from the circumstances of his ordination, he was a Semi-Arian and a follower of Eusebius in 341, at a later period of his life he departed from this position, and vigorously opposed the teaching of his former leader. He appears to have joined the Homoian party, which took shape and acquired influence before the council of Constantinople in 360, where he adhered with the rest of the council to the creed of Ariminum, with the addendum that in future the terms *inhomoiotus* and *ousia* should be excluded from Christological definitions. Thus we learn from Auxentius that he condemned Homoiousians and Homoiousians alike, adopting for himself the Homoian formula, "filium similem esse patri suo." This Arian form of Christianity was imparted by Ulphilas and his disciples to most of the tribes of the Gothic stock, and persisted among them, in spite of the persecution, hatred, and political disasters it involved, for two centuries.

The other legacy bequeathed by Ulphilas was of less questionable value. His version of the Scriptures (see GOTHIC LANGUAGE, vol. x. p. 852) is his greatest monument as a way-breaker and a scholar. By it he became the first to raise a barbarian tongue to the dignity of a literary language; and the skill, knowledge, and adaptive ability it displays make it the crowning testimony of his powers as well as of his devotion to his work.

The personal qualities of the man may be inferred from his pupil's description of him as "of most upright conversation, truly a confessor of Christ, a teacher of piety, and a preacher of truth,—a man whom I am not competent to praise according to his merit, yet altogether keep silent I dare not."

pädie, vol. xvi., 1885; Id., *De Fontibus Ulfilæ Arianismi*; Bessell, *Das Leben des Ulphilas*, 1880; C. A. Scott, *Ulphilas, Apostle of the Goths*, 1885. See also "Gothic Language" under GOTH.

(C. A. S.)

ULM, an ancient and important commercial town in Würtemberg, and an imperial fortress of the first class, is situated on the left bank of the Danube, in a fertile plain at the foot of the Swabian Alps, 45 miles to the south-east of Stuttgart and 63 miles to the north-west of Munich. The town, quaintly built with narrow and confined streets, still preserves the dignified and old-fashioned appearance of an ancient imperial town, and contains many mediæval buildings, both of historic and of artistic interest. Among these, besides numerous handsome private houses, are the town-house, of the 16th century, in the Transition style from late Gothic to Renaissance; the Kornhaus and market-buildings; the Ehingerhaus or Neubronnerhaus, now containing the industrial museum; the "new building," erected in 1603 on the site of a palace of Charlemagne; and the commandery of the Teutonic order, built in 1712–18 on the site of a habitation of the order dating from the 13th century. By far the most important and conspicuous building in Ulm, however, is the magnificent early Gothic cathedral, next to the cathedral of Cologne the largest church in Germany, and capable of containing 30,000 people. Begun in 1377, and carried on at intervals till the 16th century, the building was long left unfinished; but in 1844 the work of restoration and completion was undertaken, and has steadily progressed ever since. Ulm cathedral has double aisles and a pentagonal apsidal choir, but no transepts. Its length (outside measurement) is 464 feet, its breadth 159 feet; the nave is 136 feet high and 47½ wide; the aisles, which are covered with rich net-vaulting, are 68 feet in height. The massive and richly decorated square tower in the centre of the west façade, for centuries terminated by a temporary spire, is now being completed according to the original plans, by the addition of an octagonal story and a tall open spire, which is to be carried up to the height of 534 feet. The towers of the choir have also been rebuilt in the course of the present restoration; they are 282 feet high. The interior, which is unusually well lighted, produces an impression of much dignity from the great height of the nave, the absence of obtrusive decoration, and the massive manner in which the walls and piers are treated. It contains some fine stained glass, the largest organ in Germany (1856), and a number of interesting old paintings and carvings by Syrlin, Engelberger, and other masters of the Swabian school. The cathedral belongs to the Protestant Church. Trinity Church dates from 1617–21; and there are also a Roman Catholic church and a modern synagogue in the town. The Danube, joined by the Iller just above the town and by the Blau just below, becomes navigable at this point, so that Ulm occupies the important commercial position of a terminal river-port. The trade, especially in wood and grain, has an upward tendency; and the Ulm market for leather and cloth is also rising in importance. Ulm is famous for its vegetables (especially asparagus), barley, beer, pipe-bowls, and sweet cakes (Ulmer Zückerbrot). Bleaching, brewing, and brass-founding are carried on, as well as a large miscellany of manufactures, including hats, metal goods, agricultural implements, tobacco and cigars, cement, paper, and chemicals. The population in 1886 was 33,611.

The various routes which converge at Ulm have made it at all times a strategic point of great importance, and it has long been a fortress of the first rank. In 1844–59 the German Confederation carefully fortified it with walls, ramparts, and ditches, and in 1876 the new German empire added a very comprehensive outer girdle of detached forts, culminating in the powerful citadel of Wilhelmshurg. The defensive works embrace also the Bavarian town of Neu-Ulm (7823 inhabitants), on the opposite bank of the Danube, united with the older city by two stone bridges. Ulm is thus the basis of operations for the German army behind the Black Forest,

and can easily shelter a force of 100,000 men; its peace garrison is 5600.

Ulm is mentioned as early as the year 854. It subsequently became a free imperial city, and the leading town in Swabia. In the 15th century it attained the summit of its prosperity, and ruled over a district of many square miles, with a population, rural and urban, of about 60,000. Towards the end of the Middle Ages it frequently appears at the head of various Swabian leagues. In 1530 it adopted the Augsburg Confession. In 1803 it passed to Bavaria, and in 1810 to Württemberg. In 1805 General Mack, with 33,000 Austrians, capitulated to Napoleon at Ulm. Ulm is remarkable in the history of German literature as the spot where the "meistersänger" lingered longest, preserving, without text and without notes, the traditional lore of their craft. In 1830 there were twelve "meistersänger" alive at Ulm; but in 1839 the four survivors formally made over their insignia and guild property to a modern singing society, and closed the record of "Meistergesang" in Germany. The last formal meeting of the Nuremberg "meister" took place in 1770.

ULPIANUS, DOMITIUS, Roman jurist, was of Tyrian ancestry, but the time and place of his birth are unknown. He made his first appearance in public life as assessor in the *auditorium* of Papinian and member of the council of Septimius Severus; under Caracalla he was master of the requests. Elagabalus deprived him of his functions and banished him from Rome, but on the accession of Alexander (222) he was at once recalled and reinstated, and finally became the emperor's chief adviser and *præfectus prætorio*. His curtailment of the privileges granted to the prætorian guard by Elagabalus provoked their enmity, and several times he only narrowly escaped their vengeance; ultimately, in 228, he was murdered in the palace, in the course of a riot between the soldiers and the mob.

Ulpian's period of literary activity extended from about 211 to 222 A.D. His works include *Ad Sabinum*, a commentary on the *jus civile* in over fifty books; *Ad Edictum*, a commentary on the Edict, in eighty-three books; collections of Opinions, Responses, and Disputations; books of Rules and Institutions; treatises on the functions of the different magistrates,—one of them, the *De Officio Proconsulis Libri X.*, being a comprehensive exposition of the criminal law; monographs on various statutes, on testamentary trusts, and a variety of other works. His writings altogether have supplied to Justinian's *Digest* about a third of its contents, and his commentary on the Edict alone about a fifth. As an author he is characterized by doctrinal exposition of a high order, judiciousness of criticism, and lucidity of arrangement, style, and language. *Domitii Ulpiani Fragmenta*, consisting of twenty-nine titles, were first edited by Tilius (Paris, 1549). There are modern editions by Hugo (Berlin, 1834) and Böcking (Bonn, 1836), the latter containing fragments of the first book of the *Institutiones* discovered by Endlicher at Vienna in 1835.

ULRICI, HERMANN (1806–1884), one of the most active philosophical writers in Germany since Hegel's death, was born at Pforten, Prussia, on March 23, 1806. Educated for the law, he gave up his profession upon the death of his father in 1829, and after four years of further study, devoted to literature, philosophy, and science, qualified as a university lecturer. In 1834 he was called to a professorship at Halle, where he remained till his death on the 11th January 1884. His first works were in the domain of literary criticism. His treatise *On Shakespeare's Dramatic Art* (1839) has been translated into English. In 1841 he published a work *Ueber Princip u. Methode der Hegelschen Philosophie*, in which he subjected Hegel's system to a severe criticism. The critical attack was continued in the *Grundprincip der Philosophie* (1845–6), which at the same time expounds his own speculative position; to this must be added as complementary his *System der Logik* (1852). His later works, dealing with perennial problems of philosophy, have found a more extended circle of readers. Such are *Glauben und Wissen* (1858), *Gott und die Natur* (1862, 3d ed. 1875), *Gott und der Mensch* (2 vols., 1866–73, 2d ed. 1874). From 1847 onward Ulrici was associated with the younger Fichte in the editorship of the *Zeitschrift für Philosophie*.

His philosophical standpoint may be characterized as a reaction from the pantheistic tendency of Hegel's idealistic rationalism

towards a more pronouncedly theistic position. The Hegelian identity of being and thought is also abandoned and the truth of realism acknowledged, an attempt being made to exhibit idealism and realism as respectively incomplete but mutually complementary systems. Ulrici's later works, while expressing the same views, are largely occupied in proving the existence of God and the soul from the basis of scientific conceptions, and in opposition to the materialistic current of thought then popular in Germany.

ULSTER. See IRELAND.

ULTRAMARINE, a magnificent blue pigment, which occurs in nature as a proximate component of LAPIS LAZULI (*q.v.*). Lapis lazuli has long been known as a precious stone, and highly valued as such, and as early at least as the 11th century the art of extracting a blue pigment from it was practised. From the beginning of the 16th century this pigment began to be imported into Europe from "over the sea," as *azurrum ultramarinum*. To extract it, the stone, after having been powdered coarsely, is heated to redness and thrown into cold water to facilitate its conversion into a very fine powder, which is next treated with dilute acetic acid to remove the carbonate of lime which is present in almost all specimens. The insoluble blue residue is mixed up into a "dough" with a composition of resin, pitch, and linseed oil, and this dough is then kneaded under water, which is renewed as long as it runs off with a blue colour. The blue liquor, when allowed to stand, deposits a fine precipitate, which is collected, washed, dried, and sold as ultramarine. As the yield amounts to only 2 to 3 per cent. of the mineral used, it is not surprising to learn that the pigment used to be weighed up with gold. It was valued chiefly on account of its brilliancy of tone and its inertness in opposition to sunlight, oil, and slaked lime (in fresco-painting).

Lapis lazuli has the composition of a double silicate of lime and soda combined with sulphates and sulphides of the metals named. Of the many analyses made (compare LAPIS LAZULI) we quote the following, carried out by Schultz in Rammelsberg's laboratory:—combined sulphur (not SO₃), 3.16; combined sulphuric acid, SO₃, 5.67; silica, 43.26; alumina, 20.22; oxide of iron, calculated as Fe₂O₃, 4.20; lime, 14.73; soda, 8.76.

In 1814 Tassaer observed the spontaneous formation of a blue compound, very similar to ultramarine, if not identical with it, in a soda-furnace at St Gobain, which caused the "Société pour l'Encouragement d'Industrie" to offer a prize for the artificial production of the precious colour. The problem was solved almost simultaneously by Guimet and by Christian Gmelin, then professor of chemistry in Tübingen; but while Guimet kept his process a secret (it has indeed never become known) Gmelin published his, and thus became the originator of an industry which flourishes to this day chiefly in Germany. There are very few ultramarine works in other countries, and none, as far as we know, in Great Britain. The raw materials used in the manufacture are—(1) iron-free kaolin, or some other kind of pure clay, which should contain its silica and alumina as nearly as possible in the proportion of 2SiO₂:Al₂O₃ demanded by the formula assigned to ideal kaolin (a deficit of silica, however, it appears can be made up for by addition of the calculated weight of finely divided silica); (2) anhydrous sulphate of soda; (3) anhydrous carbonate of soda; (4) sulphur (in the state of powder); and (5) powdered charcoal or relatively ash-free coal, or colophony in lumps. The numerous modes of manufacture may be viewed as modifications or combinations of three processes.

(1) In the *Nuremberg process* the soda is used as sulphate, or partly as such and partly as carbonate. The following recipe gives an idea of the proportions in which the materials are used:—kaolin (calculated as anhydrous matter) 100 parts; calcined sulphate of soda 83 to 100 (or 41 of sulphate and 41 of carbonate); charcoal 17; powdered sulphur 13. These ingredients are mixed most intimately; they are then rammed tight into fire-clay crucibles and kept at a nearly white heat for 7 to 10 hours, access of air being prevented as far as possible. The product obtained is a greyish or yellowish green mass, which is soaked in and washed with water; the porous residue is ground very fine in mills, again washed, dried, and again ground in the dry state and passed through sieves. The product at this stage has a green colour, and is sometimes sold as "green ultramarine," although it has not a high standing amongst green pigments. For its conversion into blue ultramarine it is heated with sulphur in the presence of air to a relatively low temperature. Of the various apparatus used for this important stage of the manufacture, the easiest to describe is a large muffle, heated from the outside. On its floor the green ultramarine is spread out to a depth of 2½ to 3 inches, and heated (with closed doors) to a

temperature at which sulphur powder when thrown in catches fire spontaneously. This temperature being maintained, a shovelful of sulphur is thrown in and allowed to burn off while the mass is being constantly agitated with iron rakers. Another dose of sulphur is then added, and so on until a sample taken out is found to have come up to the highest attainable brilliancy and depth of blue. The product is then lixiviated with water, which removes a deal of sulphate of soda formed in the process; it is then ground up very fine, and finally subjected to elutriation to produce a graduated series of ultramarines of different degrees of fineness. In some works the process of sulphuration is divided into two or more periods, after each of which the product is washed, dried, and ground before being returned to the muffle to produce a higher degree of homogeneity.

(2) In the *carbonate of soda process* the soda is used solely, or at least principally, in the carbonate form. The following is one of many recipes:—kaolin (calculated as anhydrous matter) 100; carbonate of soda 100; charcoal 12; sulphur 60. The mixture is heated in a reverberatory furnace to form in the first instance a white mass, which is so porous that it readily passes, by oxidation, into green and partly even into blue ultramarine. Green ultramarine, saleable as such, cannot be produced in this manner. The half-blue product is finished by sulphuration pretty much as explained above for the Nuremberg process. Well-made soda-ash ultramarine has a richer colour than the Nuremberg variety.

(3) *Silica ultramarine* is soda-ash ultramarine in whose preparation a quantity of finely divided silica, equal to 5 to 10 per cent. of the weight of the kaolin, has been added. It is distinguished by a reddish tinge, which is the more fully developed the greater the proportion of added silica. It is more highly proof against the action of alum solution than non-siliceous ultramarine is.

Since 1873 the Nuremberg works have been producing four varieties of magnificently violet ultramarine. The mode of manufacture has not transpired. At the Paris Exhibition in 1867 a magnificent block of ultramarine exhibited by the Kaiserslautern works attracted attention. In its manufacture the roasting (blueing) process is said to have been continued for three weeks.

Artificial, like natural, ultramarine has a magnificently blue colour, which is not affected by light nor by contact with oil or lime as used in painting. Hydrochloric acid at once bleaches it with liberation of sulphuretted hydrogen gas and milk of sulphur. The natural pigment is proof against dilute acetic acid and solution of alum; the artificial pigment is even alum-proof only in a higher or lower relative sense. Hence there is room for progress in one direction at least. The composition of the pigment is quite similar to that of lapis lazuli; but the constitution of both is still a chemical enigma. It is remarkable that even a small addition of zinc-white (oxide of zinc) to the reddish varieties especially causes a considerable diminution in the intensity of the colour, while dilution with artificial precipitated sulphate of lime ("annalin") or sulphate of baryta ("blanc fix") acts pretty much as one would expect. Ultramarine being very cheap (it sells at 7d. to 10d. per lb), it is largely used for wall painting, the printing of paper hangings and calico, &c., and also as a corrective for the yellowish tinge often present in things meant to be white, such as linen, paper, &c. Large quantities are used in the manufacture of paper, and especially for producing that kind of pale blue writing paper which is so popular in Great Britain. Only the very finest ultramarine can be used for paper tinging, because the least admixture of coarse particles becomes visible in the paper as dark spots or stains.

ULUGH BEG, MIRZA MOHAMMED BEN SHAH ROK (1394–1449), astronomer, grandson of TIMUR (*q.v.*), succeeded his father as prince of Samarkand in 1447, after having for years taken part in the government, and was murdered in 1449 by his eldest son. He occupied himself with astronomical pursuits, and erected an observatory at Samarkand, from which were issued tables of the sun, moon, and planets, with an interesting introduction, which throws much light on the trigonometry and astronomical methods then in use (*Prolégomènes des Tables Astronomiques d'Ouloug Beg*, ed. by Sédillot, Paris, 1847, and translated by the same, 1853). The serious errors which he found in the Arabian star catalogues (which were simply copied from Ptolemy, adding the effect of precession to the longitudes) induced him to redetermine the positions of 992 fixed stars, to which he added 27 stars from Al Súfi's catalogue, which were too far south to be observed at Samarkand. This catalogue, the first original one since Ptolemy, was edited by Th. Hyde at Oxford in 1665 (*Tabulæ Longitudinis et Latitudinis Stellarum Fixarum ex Observatione Ulugbeighi*), and in 1843 by Baily in vol. xiii. of the *Memoirs* of the Royal Astronomical Society.

ULVERSTON, a market-town in the north-west of Lancashire, England, is picturesquely situated near Morecambe Bay, on the borders of the Lake district, 9 miles north-east of Barrow-in-Furness, and 256 north-west of London. The town bears small evidence of its great antiquity. The principal streets branch from the market-place, and the houses built of stone are generally rough-cast and whitened. A rivulet flows through the town. The church of St Mary, founded in 1111, retains the south door of the original building in the Transition style, but the greater portion of the structure is Perpendicular, of the time of Henry VIII. It consists of chancel, nave, aisles, south porch, and embattled western tower, and contains an altar-tomb with recumbent figure of Walter Sandys of Conishead, dated 1588. After the destruction of Furness Abbey, Ulverston succeeded Dalton as the most important town in Furness, but the rapid rise of Barrow within recent years has relegated it to quite a secondary place. Formerly it had a considerable trade in linens, checks, and gingham, but this has greatly fallen off. It possesses, however, large iron and steel works (North Lonsdale Iron and Steel Company), a large chemical work, an extensive paper manufactory, a bolt manufactory, breweries, tanyards, and wooden hoop manufactories. The population of the urban sanitary district (area 3120 acres) in 1871 was 7607, and in 1881 it was 10,008.

Early in the 12th century the lordship of Ulverston came into the possession of Stephen, earl of Boulogne, afterwards king of England, by whom it was presented to the monks of Furness Abbey as part of the endowment. In 1196 the *ville* of Ulverston was granted by the abbot of Furness to William de Lancaster, first baron of Kendal. In 1280 it obtained the charter of a market. The town became escheated to the abbot of Furness as chief lord in 1342, but this escheatment was suspended by Edward II. in favour of John de Coupland, who captured David II. of Scotland at the battle of Durham. After his death it reverted to the abbey. It is now in the possession of the family of Buccleuch.

ULWAR, an alternative form of ALWAR (*q.v.*).

ULYSSES. See ODYSSEUS.

UMAÑ, a district town of Russia, in the south of the government of Kieff, is now a small industrial and trading town, with 15,400 inhabitants, many of whom are Jews, who carry on an active trade in the export of corn, spirits, &c. It has a remarkable park (290 acres), planted in 1796 by the orders of Count Potocki, in connexion with which a gardening school is maintained.

Uman was founded towards the beginning of the 17th century as a fort against the raids of the Tartars. The Cossacks of the Ukraine, who kept it, revolted against their Polish rulers about 1665, and had to sustain a fierce siege. In 1674 it was plundered and most of its inhabitants murdered by the Ukrainians and Turks, during the wars for the hetmanship. In 1712 its last inhabitants were transferred by Peter I. to the left bank of the Dnieper. But by the end of the 18th century, when it again became the property of the Potockis, it was re-peopled and became one of the busiest trading towns of Little Russia. In 1768, when the Cossacks revolted anew against their Polish serf proprietors, they took Uman and murdered most of its inhabitants.

UMBALLA, an alternative form of AMBÁLA (*q.v.*).

UMBER. See PIGMENTS.

UMBRELLA now means a portable protector from rain, while the name parasol is given to the generally smaller, lighter, and more fanciful article carried by ladies as a sun-shade. But primarily the umbrella (*ombrella*, Ital. dim. from Lat. *umbra*, shade) was a sun-shade alone,—its original home having been in hot brilliant climates. In Eastern countries from the earliest times the umbrella was one of the insignia of royalty and power. On the sculptured remains of ancient Nineveh and Egypt there are representations of kings and sometimes of lesser potentates going in procession with an umbrella carried over their heads; and throughout Asia the umbrella had, and still has, something of the same significance. The Mahratta princes of India had among their titles "lord of

the umbrella." In 1855 the king of Burmah in addressing the governor-general of India termed himself "the monarch who reigns over the great umbrella-wearing chiefs of the Eastern countries." The baldachins erected over ecclesiastical chairs, altars, and portals, and the canopies of thrones and pulpits, &c., are in their origin closely related to umbrellas, and have the same symbolic significance. In each of the basilican churches of Rome there still hangs a large umbrella.

Among the Greeks and Romans the umbrella (*σκιᾶς, σκιᾶδειον, umbraculum, umbella*) was used by ladies, while the carrying of it by men was regarded as a sign of effeminacy. Probably in these southern climes it never went out of use, and we find from allusions by Montaigne that in his day its employment as a sun-shade was quite common in Italy. The umbrella was not unknown in England in the 17th century, and was already used as a rain protector. Michael Drayton, writing about the beginning of the 17th century, says, speaking of doves:—

"And, like umbrellas, with their feathers
Shield you in all sorts of weathers."

Although it was the practice to keep an umbrella in the coffee-houses early in the 18th century, its use cannot have been very familiar, for in 1752 Colonel Wolfe, writing from Paris, mentions the carrying of them there as a defence against both rain and sun, and wonders that they are not introduced into England. The traveller Jonas Hanway, who died in 1786, is credited with having been the first Englishman who habitually carried an umbrella. That practice he began thirty years before his death; at first he was singular, and his habit was derided, but he lived to see his example commonly followed.

The umbrella as at first used, based on its Eastern prototype, was a heavy ungainly article which did not hold well together, and no little ingenuity has been exercised to bring it into the elegant, compact, and strong form which is now quite common. The early umbrella had a long handle, with ribs of whalebone or cane, very rarely of metal, and stretchers of cane. The jointing of the ribs and stretchers to the stick and to each other was very rough and imperfect. The covering material consisted of oiled silk or cotton, heavy in substance, and liable to stick together in the folds. Gingham soon came to be substituted for the oiled cloth, and in 1848 William Sangster patented the use of alpaca as an umbrella covering material. One of the most notable inventions for combining lightness, strength, and elasticity in the ribs of umbrellas was the "Paragon" rib patented by Samuel Fox in 1852. It is formed of a thin strip of steel rolled into a U or trough section, a form which gives great strength for the weight of metal. The use of such ribs, combined with the notched rings and runners which give a separate hinge and joint to each rib and stretcher, and with the thin but tough covering materials now in use, has principally contributed to the strength, lightness, and elegance which ordinary umbrellas now present. Umbrella silk is principally made at Lyons and Crefeld; but much of it is so loaded in dyeing that it cuts readily at the folds. Textures of pure silk or of silk and alpaca mixed have better wear-resisting properties.

UMBRIA (*Ὀμβρική, Ὀμβρικοί, Ὀμβροί, UMBRI*). The early Greeks applied the name *Ὀμβρική* to all central and northern Italy. Herodotus (iv. 49) speaks of it somewhat vaguely, as if it extended up to the Alps. The Umbrians probably extended across central Italy from sea to sea down as far as Latium. Pliny (iii. 13, 19) tells us that the Umbri were considered the most ancient nation of Italy (*antiquissima gens Italix*), by which he probably means, of the Italian stock. The Greek writers included under the name of Umbria the district known in later times as Picenum. Pseudo-Scylax makes Umbria march with Samnium, and describes Ancona as a city of Umbria. The Umbrians seem to have found the Siculi and Liburni in occupation of the land into which they advanced, the former holding the parts lying towards the interior, the latter people the district along the Adriatic. The Umbrians were one of the chief peoples of that branch of the Indo-European family which had entered Italy from the north

and driven out and absorbed the older inhabitants. They were more closely connected with the Samnites and Oscans than with the Latin stock, as is shown by their language. Their possession of the fertile regions of upper Italy exposed them to the constant assaults of fresh bodies of invaders, pressing on over the Alps, and perhaps likewise from the seaboard. Their force was extended over a wide area, and thus too weak to withstand the attacks from various sides to which they were exposed. Thus their extensive territory was gradually reduced by the successive encroachments of other peoples. First came the Etruscans, who according to Herodotus (i. 94) were Lydians, who established themselves in the land of the Umbrians. From which side of Italy they made their invasion, whether from the mouth of the Po or from the western coast of what later became Etruria, or whether from both, we have no means of determining. That the Umbrians did not yield without a struggle we cannot doubt. It was only after three hundred of their towns had been captured by the Etruscans that they succumbed. Nevertheless they still retained considerable influence in upper Italy, which, according to Strabo (v. 216), continued down to the time of the Roman conquest. For he says that there was a large Umbrian element in the Roman colonies in the region of the Po, as also some Etruscan. For, according to him, the Umbrians and Etruscans lived in a continual rivalry for the pre-eminence, so that if the one people made an expedition northwards, the other determined not to be outdone. So when the Etruscans had marched against the barbarians who dwelt near the Po, and had soon again been expelled owing to their effeminacy, the Umbrians in turn marched against the conquerors of the Etruscans. In consequence of this alternating struggle for these regions they planted many colonies, some Etruscan, others Umbrian. Most of the colonies were Umbrian because the Umbrians lay closer to the disputed territory. Thus, even though they lost the sovereignty, the Umbrian race probably continued to form a considerable portion of the population of a wide extent of country. At all events, at the time of the Gaulish inroad the Etruscans seem to be in possession of the mouth of the Po. At this time, therefore, Umbria as a state consisted of the region bounded on the W. by the Tiber, on the S. by the Sabines, on the E. by Picenum and the Adriatic, while on the N. it extended close up to the southern or Spinetic mouth of the Po. Scylax describes the Etruscans as extending from the Tyrrhenian Sea to the Adriatic, and represents them as in possession of the ancient Greek town of Spina. How much farther south the Etruscan sway had once reached we cannot determine, but that they had once held this region, as far as Ravenna at least, is rendered probable by the tradition that Ravenna had been founded by a colony of Thessalians who, not brooking the insulting treatment which they received from the Etruscans, gladly admitted some Umbrians, who thus became the possessors of the city. When the great Gaulish inroad took place at the beginning of the 4th century B.C. Etruscans and Umbrians alike suffered severely. Some of the Celtic tribes crossed the Po and formed permanent settlements. The Ananes settled in the Apennines, the Boii between the former and the Adriatic; next came the Lingones; and finally the Senones occupied the seaboard of the Adriatic as far as the Rubicon. This region in Roman times was known as the Ager Gallicus (Polybius, ii. 16). But it was not only in the north and west that the Umbrians had been driven back. The early Greeks had included under the name of Umbria the district along the Adriatic, afterwards known as Picenum. This consisted of a fertile region, extending from beyond Ancona to the river Matrinio. It is not improbable that the Picentes issued from the Sabine region. Tradition alleged

that the Picentes, led by the woodpecker (*picus*) of Mars, marched forth to occupy what is now the March of Ancona. But it was probably only after a long struggle that this conquest was effected, for from another tradition we learn that the Sabines, after carrying on war against the Umbrians for a long time, at length vowed a sacred spring, and dedicated all the produce of the year to the gods. Then at length they became victorious (Strabo, v. 250). Thus, by the advance of the Gauls from the north and the Picentes from the south, the Umbrians were shut off from the seaboard, and confined to the district known as Umbria in historical times. When Rome began the consolidating of Italy, Umbria consisted of the region bounded by the Ager Gallicus on the N., by Etruria (the Tiber) on the W., by Picenum on the E., and by the Sabines on the S. The Umbrians kept a desperate hold of this district, which lies between the two arms of the Apennines. This position indicates of itself that they had been driven before stronger foes. Henceforward they play but an insignificant part in Italian history. This is explained by the physical formation of their country. It is an extremely mountainous region, with a few small plains between, which were noted for their fertility. Hence arose a number of small but thriving communities, none of which had the capacity of developing into a leading state such as Rome became for the Latins. Their want of seaports likewise excluded them from trade, the mouths of all the rivers which flowed from their country being in the hands of their enemies.

Of the Umbrians' political and municipal organization little is known. In addition to the city (*lota*) they seem to have had a larger territorial division in the *tribus* (trifu, acc.) as we gather from Livy (xxxi. 2, per Umbrian quam tribum Sapiuinum vocant; cf. xxxiii. 37) and from the Etruscan Tables (trifor Tarsinates, vi. B. 54). From the fertility of their land their communities were very prosperous. The olive and vine flourished in their valleys; they grew spelt abundantly; and the boars of Umbria were famous. Ancient authors describe the Umbrians as leading effeminate lives, and as closely resembling their Etruscan enemies in their habits (Theopompus, fragm. 142; Pseudo-Scymnus, 366-8). It is almost certain that each race influenced and modified the other to a large extent. Mommsen has pointed out that the names of many towns in Etruria are Umbrian, a fact which shows how persistent even after conquest was their influence in that region. On the other hand, we have conclusive proof of strong Etruscan influences in Umbria. For instance, they undoubtedly borrowed their alphabet and the art of writing from the Etruscans. Their writing runs from right to left. The alphabet consists of nineteen letters. It has no separate symbols for O, G, Q; the aspirates ϕ and χ are wanting; on the other hand, it possesses forms for Z and V, and has likewise the Etruscan f (8). It also has a symbol d peculiar to itself for expressing the sound of palatal *k* when followed by either *e* or *i*. It is also very probable that they borrowed the art of coining money from Etruria. Two towns are known to have issued coins, which consist entirely of bronze, and belong almost entirely to the series of *as grave*. The most important is that of Tuder (Todi), which must have been a place of some note. It was a strong fortress on the left bank of the Tiber on the confines of Etruria. Iguvium (Gubbio), which struck coins after the standard of Tuder, was a strong place likewise on the western or Etruscan side of the Apennines. The fact that it is only in towns on the side next Etruria that a coinage is found indicates that it was from the Etruscans they borrowed the art. The Umbrians counted their day from noon to noon. But whether they borrowed this likewise from the Etruscans we do not know (Pliny, ii. 77). In their measuring of land they employed the *vorvus*, a measure common to them and the Oscans (Frontinus, *De Limit.*, p. 30), $\frac{3}{4}$ of which went to the Roman *jugerum*. When the Romans undertook the conquest of Italy, the most feeble resistance of all was offered to them by the Umbrians. In the great struggle between the Samnite confederacy and Rome Umbria played an insignificant part. It is probable that all through the Second Samnite War their sympathies were altogether on the side of their Samnite kinsmen, and that some assistance was afforded by individual communities. It is not unlikely therefore that it was with a view to keep the Umbrians in check that the Romans planted a colony at Nequinum on the Nar, whose inhabitants were known as Nartes Interamnates, and who are included with the Etruscans, Iapydes, and Tadinates in the list of persons who were forbidden to be present at the sacred-rites of Iguvium. At length in 308 B.C. the Umbrians made a vigorous effort to aid the Samnites, which, had

it taken place earlier in the war, might have had the most important influence on the issue of the struggle. As it was, it came too late; the Etruscans had already laid down their arms. The Umbrians, who threatened to march on Rome, were intercepted by Rullianus with the Roman army from Samnium on the upper Tiber, a step which the Samnites now broken could not prevent; and this was sufficient to disperse the Umbrian levies. When the Third Samnite War broke out, the Umbrians took no active part in its operations; but how their sympathies lay is evident from their affording a ready passage to the Samnite army under Gellius Egnatius on its march to Etruria, 296 B.C. When the battle of Sentinum (295) finally crushed the Samnites and Etruscans, Umbria remained in the hands of the Romans. Henceforward the process of Latinizing went on steadily, for by the 1st century B.C. we find them employing the Latin alphabet in copies of the ancient sacerdotal ritual of Iguvium (see EUGUBINE TABLES). We know that the Oscan language only finally expired in the 1st century of our era, and there is no reason for believing that the Umbrian had disappeared much earlier. When the Romans conquered the Senones, 280 B.C., the Ager Gallicus was restored to Umbria, and both together formed under the empire the sixth region of Italy.

Strabo (v. 227) regards Ravenna as the boundary of Umbria. The Via Flaminia passed up through it from Oriculum to Ariminum, along which lay the important towns of Narnia (Narni) Carsulæ (Carsigliano), Mevania (Bevagna), Forum Flaminii, Nuceria, and Forum Sempronii. To the east lay Interamna (Terni), the probable birthplace of Tacitus, Spolegium (Spoleto), and the most important town of Camerinum on the side of the Apennines towards Picenum. On the side towards Etruria lay Tuder (Todi), Iguvium, which occupied a very advantageous position close to the main pass through the Apennines, Ameria (Amelia), and Hispellum (Spello); on the Clitumnus (Clitunno) was Assisium (Assisi), the birthplace of Propertius, whilst far to the north lay Sarsina, the birthplace of Plautus. For the position of the country in the time of Augustus, see vol. xiii. Plate V.

See Bréal, *Les Tables Eugubines*, 1875; Bücheler, *Umbria*, 1882; Kirchhoff, *Griech. Alphabet*, 4th ed., 1887; Head, *Historia Numorum*, 1887. (W. R.)

UMMERAPOORA, another form of AMARAPURA (*q.v.*).

UNAO, a British district in the Lucknow division of Oudh, India, under the jurisdiction of the lieutenant-governor of the North-Western Provinces. The area of the district is 1768 square miles, and it is bounded on the N. by Hardoi, E. by Lucknow, S. by Rai Bareilly, and W. by the Ganges. Unao is very flat, and has no features of particular interest. Rich and fertile tracts, studded with groves, alternate with stretches of waste land and plains of barren *usar*, the whole being intersected with small streams, the water from which is extensively used for irrigation. The Ganges is the only navigable river in the district. The temperature varies from about 75° to 103° in the hot weather, and from 46° to 79° in the cold season. The average annual rainfall is about 34 inches.

In 1881 the population was 899,069 (males 461,167, females 437,902); of these 830,342 were Hindus, 68,677 Mohammedans, and 49 Christians. Unao, the capital and administrative headquarters, 9 miles north-east of Cawnpore, had 9509 inhabitants. The cultivated area of Unao amounted in 1885-86 to 598,131 acres, and 289,356 acres were returned as cultivable. The principal crops are rice, wheat, and other food grains, cotton, sugar-cane, and indigo. The cultivation is mainly dependent on irrigation. The principal exports are grain of all kinds, gúr, ghi, tobacco, and a little indigo and saltpetre; and the chief imports are piece goods, salt, iron, cotton, spices, &c. The gross revenue of the district in 1885-86 amounted to £183,083, the land yielding £144,914. During the mutiny of 1857-58 Unao was the scene of several severe engagements between General Havelock's little army and the rebels. On the death of Rájá Jasa Singh, one of the leading rebels, and the capture of his two sons, the whole family estates were confiscated, and the villages either restored to their former owners or given to other landholders for their loyalty.

UNDULATORY THEORY. See OPTICS and WAVE THEORY.

UNGVAR, chief town of the county Ung, in the north-east of Hungary, stands on the river Ung. It is the seat of the bishop of Munkács, and has a fine Greek cathedral, an episcopal seminary, a lyceum, a gymnasium, and also a teachers' college, a county hall, and an interesting ancient castle. The town and district produce good wine in large quantity, and abound in mineral springs. There is a good trade in timber and china clay. The population in 1886 was 13,460.

UNICORN, an animal with one horn. The name is applicable and has sometimes been applied to the rhinoceros, which is, for example, the Sumatran unicorn of Marco Polo. But the figure usually associated with the name is the well-known heraldic one of an animal with the form of a horse or ass, save that a long straight horn with spiral twistings, like the tusk of the narwhal, projects from its forehead. The belief in the existence of a one-horned animal of this kind goes back to Aristotle (*Part. An.*, iii. p. 663), who names as one-horned "the oryx and the Indian ass." Later descriptions of the Indian unicorn, e.g., that of Ælian (*Nat. An.*, xvi. 20), are plainly influenced to some extent by accounts of the rhinoceros, but the authority of Aristotle determined the general form ascribed to the animal. The twisted horn, of which Ælian already speaks, seems to have been got by referring to Aristotle's unicorn actual specimens taken from the narwhal; see Yule's *Marco Polo*, ii. 273. The ancient and mediæval lore of the subject may be seen in Bochart, *Hierozoicon*, iii. 26. The familiar legend that the unicorn could be taken only by the aid of a virgin obtained currency through the *Physiologus* (see vol. xix. p. 7). The English Bible, following the Septuagint (*μονόκερως*), renders the Hebrew *rēm* (רֵמ) by "unicorn." But two horns are ascribed to the *rēm* in Deut. xxxiii. 17, and the Hebrew word reappears in Arabic as the name of the larger antelopes, probably the *Antelope leucoryx*, while in Assyrian the *rīmu* appears to be the wild ox. There are recent fossil remains in the Lebanon both of *Bos primigenius* and *Bison urus*, though both have been long extinct in Palestine.

UNITARIANISM. The term Unitarianism in its widest sense includes certain lines of the great religious and theological movement or revolution of the Reformation in the 16th century, when this is regarded as the commencement of the process of the humanization of theology and ethics on the basis of the autonomy of the human mind. In another sense the term stands for a set of theological opinions, more or less variable, and yet in their general drift connected, some of them as old as Christianity, and one section of which only is indicated by the term when used as synonymous with Antitrinitarianism. But there is another meaning of the term, a still narrower one, and to Unitarianism in this sense this article must be confined. We must limit ourselves to a brief account of Unitarianism as it appears in ecclesiastical organizations in separation from the orthodox churches. This treatment of the subject is of course incomplete, and would be misleading were the incompleteness not expressly announced. For a marked feature of the late history of the Unitarian churches is the growing tendency they exhibit of working out to their logical results some of the wider principles of the Reformation to which they ultimately owe their origin, rather than the design of formulating and propagating systems of theology. To not a few modern Unitarian leaders the bond which connects them with a specifically Unitarian organization is the spirit and tendency of the larger movement for which it happens to provide freer play than the orthodox churches, while they repudiate the imputation of belonging to a dogmatic sect. Modern Unitarians have also, both in Europe and America, emphatically and successfully resisted the inclination of some of their number to lay down, though in the most general terms, a creed of Unitarianism. Indeed, in opposing this inclination, it might sometimes seem as if the only essential article of Unitarianism were the maintenance of free inquiry in religion,—an impression, however, which a careful study of the history of Unitarian thought would remove. In the same way such a study would show that Unitarian churches are in agreement on many points of doctrine with early and recent theologians of all churches and sects.

This brief sketch of Unitarianism, as it has appeared in organized religious societies, takes us into but a few countries, and covers but a limited space of time. Poland, Transylvania, England, and America are the only countries in which Unitarian congregations have existed in any numbers or for any length of time. Elsewhere, either the law of the land has rendered their existence impossible, or they have been unnecessary in consequence of the substantial adoption by the existing churches of their principles and doctrines. The former was the case in Italy, Switzerland, Germany, and England in the 16th and 17th centuries, the latter to a certain extent in England in the 18th century, still more in Germany in the 18th and 19th centuries, and in Holland in the present century, as also to a large extent in France in the Reformed Church.

Poland (1565–1658).—The Unitarians, under the names of Arians, Samosatenians, Pinczowians, were formed into a separate church in 1565 by their exclusion as Antitrinitarians from the synods of the Trinitarian Protestants. Very early in the progress of the Reformation in Poland individuals had arrived at heterodox opinions on baptism and the Trinity, very much under the influence of the heterodox Italian refugees in Switzerland, some of whom visited Poland (Lelio Sozzini, 1551 and 1558; Paul Alciani, 1561; G. V. Gentile, 1561; Biandrata, 1555). Gonesius and Gregory Pauli were the first to openly preach Antitrinitarian doctrine. After their separation from the orthodox, the Polish Unitarians developed divergent views as to the nature of Christ, as to the lawfulness of paying divine worship to Him, as to the subjects of baptism (infants or adults), and as to the relation of Christians to the state. On the first point some were Arians and others Humanitarians, while those who claimed divine worship for Christ were called *Adorantes* and those of the opposite view *Nonadorantes*. An epoch in the history of the party was made by the arrival of Fausto Sozzini at Cracow in 1579 (see SOCRUS). He succeeded in converting the great majority of the churches to his views and in silencing the dissentients. Henceforth the Polish Unitarians adopted the Socinian practice of paying worship to Christ, the Socinian view of the necessity of baptism and of the Christian's duty towards the state. They rapidly became a numerous and powerful body in Poland, distinguished by the rank of their adherents, the ability and learning of their scholars, the excellence of their schools, and the superiority and wide circulation of their theological literature. Racow, the theological centre of the Socinians, with its school and printing presses, obtained a world-wide fame. It was there that the *Racovian Catechism* was published (1605 in the Polish language, 1608 in German, and 1609 in Latin). But before the death of Fausto Sozzini (1604) the situation of the Unitarians became more difficult, and in 1611 the Jesuits obtained their first open triumph over them. In the rapid course of the Catholic reaction, which was not resisted by the orthodox Protestants as long as the Socinian heretics only suffered, the church and school at Lublin, the most important place next to Racow, were first put down (1627), and Racow, with its church, school, and printing-press suffered the same fate in 1638. The final blow to the whole body followed in 1658, when all adherents of "the Arian and Anabaptist sect" were commanded to quit the kingdom within two years. A few renounced their faith, but the large majority fled into Transylvania, Prussia, Silesia, Holland, and England.

Transylvania (1568–1887).—Next to Poland Transylvania was the most important seat of Unitarianism. It was there the name was first used by the sect as its own designation, and it is there only that the sect has had a continuous existence down to our own time. It is generally considered that the Italian refugee Biandrata was the founder of Transylvanian Unitarianism, but the present representatives of the body claim for it a nobler and domestic origin. Biandrata attended John Sigismund as a physician in 1563, and under his influence Unitarianism made rapid progress. In 1568 its professors, favoured by the king and many magnates, after separating from the orthodox church, constituted themselves a distinct body under the distinguished man Francis David, who is now regarded as the apostle of true Transylvanian Unitarianism. Their principal centre was Klausenburg (Kolozsvár), where they had a large church, a college, and a printing-press. But the same conflict between a more radical and a more conservative tendency which appeared amongst the Unitarians of Poland greatly disturbed the churches of Transylvania, particularly with regard to the worship of Christ. On the side of the *Adorantes* was Biandrata, and on that of the *Nonadorantes* David. The party of David succumbed to force and fraud, and he himself died in prison a martyr to his convictions. Gradually the Socinian view prevailed, though in 1618 an old order to worship Christ required reinforcement. In the latter half of the 18th century the more logical view of David entirely disappeared. Under the Austrian dynasty the Unitarians

were often exposed to great trials, until Joseph II. secured to them their rights and privileges. An official confession of faith of the year 1787 remains, with some modifications, essentially Socinian. But of late years the Transylvanian Unitarians have been in close relation with their co-religionists in England and America, some of the ministers having been educated at Manchester New College, and in consequence their theology is becoming essentially modern. The number of members was 32,000 in 1789, in 1847 40,000, distributed in 104 parishes with 120 pastors. Their present number is 53,539 in 106 parishes. Their chief centres are Kolozsvár, Thorda, and Keresztur, where they have excellent schools.

England (1773-1887).—For two and a half centuries previous to the rise of organized Unitarianism in England, opinions commonly called by this name found numerous individual advocates and some martyrs. John Bidle (1615-62) published catechisms of Unitarian doctrine, translated Socinian works, and publicly discussed and preached an English form of Socinianism. But the severity of the law against Antitrinitarians, coupled with the gradual growth of free opinion in the Established Church and amongst the Presbyterian congregations, made the formation of separate Unitarian churches impossible, and, as was felt, less necessary for another hundred years. The adoption of a completely Humanitarian view of Christ's person by a few solitary individuals (Lardner 1730, Priestley 1767, Lindsey 1773), assisted by the awakened earnestness of the time, led to their formation. Lindsey resigned a valuable living in Yorkshire, and gathered the first professedly Unitarian church in London. Other clergymen followed his example, and amongst the Presbyterians several ministers, like Joseph Priestley, exchanged their Arian for Humanitarian views. This process went on with deep permanent effects in some of the Dissenting academies. In the year 1791 was formed the Unitarian Book Society for the distribution of literature, and several provincial associations originated about the same time. In 1806 the Unitarian Fund Society was established, with the object of promoting Unitarian Christianity by direct mission work. In 1818 arose another society for protecting the civil rights of Unitarians. These various societies were consolidated in 1825 under the name of the British and Foreign Unitarian Association, which has now its headquarters in the building formerly used as Lindsey's chapel and residence in Essex Street, London. Early in this century nearly the whole of the old Presbyterian congregations, which, unlike those of the Baptists and Independents, had undogmatic trust-deeds, passed through the stages of Arminianism and various forms of Arianism into Socinianism in its peculiar English and mainly Priestleyan form. The penal laws against Antitrinitarianism, which had long been obsolete, were repealed in 1813, and in 1844 the right of Unitarians to the chapels which they held in succession from their Presbyterian forefathers was legally secured to them by the Dissenters' Chapels Act without altering their undogmatic trust-deeds. Though these congregations, popularly known as Unitarian, on principle declined to restrict the progress of thought by imposing on either their ministers or members any dogmatic statements of belief, the generality of them adopted with some modifications the theological system of Priestley, which was a combination of Locke's philosophy with the crudest rationalistic supernaturalism. With the rise of a more spiritual philosophy in Germany, which bore fruit in England and America before the close of the second decade of the century, the theology of English Unitarianism underwent a radical change, very much in the first instance under the influence of Dr Channing's writings. Without at all sacrificing its critical and rational bent, a deeper emotional and spiritual element was introduced into it, which gradually, at the cost of some years of internal conflict, dispossessed the purely external and supernaturalistic Socinian and Priestleyan legacy. English Unitarian theology was thereby brought into close sympathy with modern scientific theology in Germany and elsewhere. This great and saving transformation was mainly due directly to James Martineau, J. J. Tayler, and J. H. Thom, aided by the writings of Channing and then of Theodore Parker. One consequence of the greater substantial agreement of the present theology of the larger number of the Unitarian churches with the scientific theology of the century is that not a few representatives of these churches disclaim the name Unitarian as one tending to perpetuate divisions which have really no right to continued existence. The main reason for continued separation from the larger liberal churches, whether Established or Dissenting, earnestly urged by many Unitarians of this class, is the use in those churches of theological formularies which modern theology regards as of historic interest only. The number of congregations in England and Wales generally described as Unitarian is about 800, nearly half of which date from between 1662 and 1750, and nearly all of which have undogmatic trust-deeds. Their constitution is purely congregational. For the education of their ministers they have Manchester New College, London (strictly undenominational), the Unitarian Home Missionary Board, Manchester, and Carmarthen College, supported and managed by the Presbyterian Board in London, but practically independent and Unitarian. The organs of the body are *The Inquirer*, *The Christian Life*, *The Uni-*

tarian Herald (weeklies), and *The Christian Reformer* (monthly). In Scotland there are 7 Unitarian congregations and 2 Universalist, the latter being, as in America, Unitarian in doctrine. In Ireland the number is about 40, being nearly all Presbyterian in constitution. They are much stronger in the north than in the south of Ireland. In the north Antitrinitarian views began to spread about 1750; but the first congregation at Dublin traces its Unitarianism back to Thomas Emlyn, who was imprisoned for his Arian opinions in 1702 at the instigation of orthodox Dissenters.

United States (1815-1887).—In the United States Unitarianism had no organized existence previous to 1815, and as in England at the present time the name has always covered great differences of opinion within a common outline of belief or common drift of religious thought. Historical American Unitarianism represents "the liberal wing of the Congregational body." Of the existing 370 churches 120 or more were originally the parish churches founded by the Puritan Congregationalists, which, like the Presbyterian congregations in England, passed gradually from Calvinism through Arminianism to Unitarianism, of which Harvard College became the spiritual centre. In 1812 there was but one church in America professedly Unitarian (that of King's Chapel, Boston), though the ministers of Boston generally held Unitarian views. In 1815 Belsham's account of the "State of the Unitarian Churches in America" (in his *Life of Lindsey*, London, 1812) led to a controversy, the issue of which was the distinct avowal of Unitarian principles on the part of the liberal clergy of New England. Dr Channing came forward as the prophet and champion of American Unitarianism, though the older he grew the more emphatically he repudiated sectarianism in every form. The Congregational body was thereby split into two sections, one of which styled themselves Unitarian Congregationalists. In 1825 the American Unitarian Association was formed, mainly for the diffusion of Unitarian literature and the support of poor congregations. At that time the Unitarian churches numbered about 122. Twenty years later they were some 280, while now they are about 370. The theological colleges of the body are the Divinity School of Harvard University, which is, like Manchester New College, undenominational, and the Theological School of Meadville. As in England so in America the theology of Unitarians has passed through marked changes, which have been attended by conflicts more or less acute. From 1815 to about 1836 a Biblical, semi-rationalistic semi-supernaturalistic theology prevailed, in the heart of which Channing's elevated ethical ideas were fermenting and slowly preparing a new birth. From 1836 forces such as Biblical criticism, Carlyle and Emerson's "transcendentalism," and Theodore Parker's "absolute religion" opened the era of modern theology, bringing American Unitarianism into living touch with the philosophy and theology of Germany. An effort in 1865 to bring the right and left wings of the body into a closer confederation with a more pronounced profession of Christianity led to the formation of a Free Religious Association on the broad basis of the love of truth and goodness. In the Western States the same controversy as to the basis of religious association has been raging for more than ten years. In May 1886 a resolution was passed by the Western Unitarian Conference by a majority of more than three-fourths adopting a purely ethical and non-theological basis. This led to a split in the body, and the formation of a new Western Association on a distinctly Christian platform. The left wing of American Unitarians show greater sympathy with recent scientific speculation and less fear of pantheistic theories than is the case with English Unitarians. The organs of the body are *The Unitarian Review* (Boston), *The Christian Register* (Boston), and *The Unitarian* (Chicago).

Literature.—On Unitarianism in general, see Fock, *Der Socinianismus*, Kiel, 1847; Wallace, *Antitrinitarian Biography*, London, 1850; *Unitarianism exhibited in its Actual Condition*, edited by J. R. Beard, London, 1846. On Socinianism and Unitarianism in Poland and Transylvania: the above works; the historical sketch of Thomas Rees in his translation of the *Racovian Catechism*, London, 1818; J. J. Tayler in *Theological Review*, Jan. 1869; *Report of an Official Visit to Transylvania*, by Alexander Gordon, London, 1879. On Unitarianism in England: Wallace's and Beard's works; J. J. Tayler, *A Retrospect of the Religious Life of England*, London, 1845, 3d ed., 1876; James Martineau, *The Three Stages of Unitarian Theology*, London, 1869; Bonet-Maury, *Early Sources of English Unitarian Christianity*, English trans., London, 1884; *Unitarian Christianity, Ten Lectures on the Positive Aspects of Unitarian Thought and Doctrine*, with preface by Rev. J. Martineau, D.D., London, 1881. On Unitarianism in America: Fock, Beard; J. H. Allen, *Our Liberal Movement in Theology*, 2d ed., Boston, 1882; *The Year-Book of the Unitarian Congregational Churches for 1887*, Boston, 1886; Count Goblet d'Alviella, *The Contemporary Evolution of Religious Thought in England, America, and India*, English trans., 1885. UNITED PRESBYTERIAN CHURCH, THE, in point of numbers the third of the Presbyterian organizations of Scotland, was formed in 1847 by the union of the United Secession and Relief Churches (see below). The doctrinal standards are those of the other Presbyterian churches of Scotland, and the formula employed at the ordination of ministers is similar to that of the Established and Free Churches; but adherence to the doctrinal standards is professed in view of the Declaratory Act of 1879, according to which signatories "are not required to approve of anything in the standards of the church which teaches or is supposed to teach compulsory or persecuting and intolerant principles in religion," and are allowed freedom of opinion on all points which, in the judgment of the church, do not enter into the substance of the faith. The denomination in 1887 consisted of 32 presbyteries and 564 congregations (518 in 1847), with a total membership of 182,063 (175,066 in 1878; 178,195 in 1883), thus representing about 14 per cent. of the population of Scotland. The number of baptisms in 1886 was 9894; there were 887 Sunday schools, with 11,994 teachers and 97,535 scholars, besides 788 advanced Bible classes, with 30,535 scholars. The total income of the church in 1886 was £373,545 (average for ten years from 1877 to 1886, £375,660); of this total £237,300 was ordinary congregational income, and £136,245 missionary and benevolent income. The average stipend paid to each minister was £259, 16s. 10d. There is a divinity hall in Edinburgh with 4 professors and (session 1887-88) 114 students. The term of study is three years. The United Presbyterian Church has missions in Jamaica (a synod with four presbyteries), Trinidad, Kaffraria, Old Calabar, India, China, Japan, and Spain. The mission staff consists of 60 ordained Europeans, 22 ordained natives, 8 medical missionaries, 3 European evangelists, and 19 female missionaries. Under these are 502 native evangelists, teachers, and other helpers. In 1886 the membership of the native congregations was 13,214 (10,215 in 1881). In Jamaica there is a theological institution. At the end of 1875 the denomination had 620 congregations, with 190,242 members, but in June 1876 98 of its congregations in England, with 20,207 members, were incorporated with the English Presbyterian Church.

HISTORY.—(1) *United Secession Church.*—The general causes which led to the first great secession from the Church of Scotland as by law established in 1688 have already been briefly indicated under PRESBYTERIANISM (see vol. xix. p. 685; compare also SCOTLAND, CHURCH OF, vol. xxi. p. 536 *sq.*). Its immediate occasion rose out of an Act of Assembly of 1732 which abolished the last remnant of popular election by enacting that, in cases where patrons might neglect or decline to exercise their right of presentation, the minister was to be chosen, not by the congregation, but only by the elders and Protestant

heritors. The Act itself had been passed by the Assembly, although the presbyteries to which it had been previously submitted as an overture had disapproved of it by a large majority; and in accordance with a previous Act (1730), which had taken away even the right of complaint, the protests of the dissentient majority were refused. In the following October Ebenezer ERSKINE (*q.v.*), minister of Stirling, who happened to be moderator of the synod of Perth and Stirling, preached a synod sermon, in the course of which he took occasion to refer to the Act in question as in his opinion unscriptural and unconstitutional.¹ Some of his expressions were objected to by members of synod because "tending to disquiet the peace of the church and impugning several Acts of Assembly and proceedings of church judicatories," and after long and keen debate it was resolved that he should be censured for them. This judgment, on appeal, was affirmed by the Assembly in May 1733, whereupon Erskine protested to the effect that he held himself still at liberty to teach the same truths and to testify against the same or similar evils on every proper occasion. This protest, in which he was joined by William Wilson, Alexander Moncrieff, and James Fisher, ministers at Perth, Abernethy, and Kinclaven respectively, was regarded by the Assembly as contumacious, and the commission of Assembly was ordered to procure its retractation or to proceed to higher censures. In November accordingly the protesting ministers were severed from their charges, their churches declared vacant, and all ministers of the church prohibited from employing them in any ministerial function. They replied by protesting that they still adhered to the principles of the church, though now obliged to "make a secession from the prevailing party in ecclesiastical courts," maintaining their continued right to discharge all the duties of the ministerial and pastoral office "according to the word of God, the Confession of Faith, and the constitution of the church," and appealing to the "first free, faithful, and reforming General Assembly of the Church of Scotland." In December 1733 they formally constituted themselves into a presbytery, but for some time their meetings were devoted almost entirely to prayer and religious conference. In 1734 they published their first, "testimony," with a statement of the grounds of their secession, which made prominent reference to the doctrinal laxity of previous General Assemblies. In 1736 they proceeded to exercise "judicial powers" as a church court, published a "judicial testimony," and began to organize churches in various parts of the country. Having been joined by four other ministers, including the well-known Ralph Erskine, they appointed Mr Wilson professor of divinity. For these acts proceedings were again instituted against them in the Assembly, with the result that, having disowned the authority of that body in an "act of declinature," they were in 1740 all deposed and ordered to be ejected from their churches. Meanwhile the members of the "Associate Presbytery" and its adherents steadily increased, until in 1745 there were forty-five congregations under its jurisdiction, and it was reconstituted into an "Associate Synod." A violent controversy arose the same year respecting the religious clause of the oath taken by burgesses in Edinburgh, Glasgow, and Perth ("I profess and allow with my heart the true religion presently professed within this realm and authorized by the laws thereof"), and resulted in April 1747 in a "breach," when two bodies were formed, each claiming to be the "Associate Synod"; those who condemned the swearing of the burgess oath as sinful came to be popularly known as "Antiburghers," while the other party, who contended that abstinence from

it should not be made a term of communion, were designated "Burghers." The Antiburghers not only refused to hold further friendly conference with the others, but ultimately went so far as to pass sentences of deposition and the greater excommunication on the Erskines and other ministers who held the opposing view.

The Associate (Antiburgher) Synod held its first meeting in Edinburgh in the house of Adam GRIB (*q.v.*) on April 10, 1747. It grew with considerable rapidity, and in 1788 had ninety-four settled charges in Great Britain and nineteen in Ireland, besides a presbytery in America. For purposes of organization it was formed in that year into four provincial synods, and took the name of "The General Associate Synod." The "new light" controversies as to the province of the civil magistrate in matters of religion led to the publication of a revised testimony in the "voluntary" sense in 1804, and in consequence M'Crie, the historian of Knox, with three other brethren, withdrew to form the Constitutional Associate Presbytery.

The Associate (Burgher) Synod held its first meeting at Stirling on June 16, 1747. The number of congregations under its charge rapidly increased, and within thirty years there were presbyteries in connexion with it in Ireland and North America, as well as throughout Scotland. In 1782 the American presbyteries took the designation of the Associate Reformed Church in America. About the year 1795 the "voluntary" controversy respecting the power of the civil magistrate in matters of religion arose within this synod also, and a large majority was found to have adopted "new light" views. This led in 1799 to the secession of the "Associate Presbytery," which in 1805 took the designation of the Associate Synod or Original Burgher Synod.²

In 1820 the General Associate or Antiburgher Synod (to the number of 129 congregations³) united with the 154 congregations of the Associate or Burgher Synod. The body thus constituted, "The United Secession Church," had increased by 1847 to 400 congregations, the whole of which united in that year with the Relief Synod to form the United Presbyterian Church.

(2) *Relief Church.*—The Presbytery of Relief was constituted in 1761 by three ministers of the Church of Scotland, one of whom was Thomas GILLESPIE (*q.v.*), who had been deposed by the Assembly in 1752 for refusing to take part in the intrusion of unacceptable ministers. The number of congregations under its charge increased with considerable rapidity, and a Relief Synod was formed in 1773, which in 1847 had under its jurisdiction 136 congregations; of these 118 united with the United Secession Church in that year. The Relief Church issued no distinctive "testimonies," and a certain breadth of view was shown in the formal declaration of their terms of communion, first made in 1773, which allowed occasional communion with those of the Episcopal and Independent persuasion who are "visible saints." A Relief theological hall was instituted in 1824.

See M'Kerrow, *History of the United Secession Church*, 1841; Struthers, *History of the Relief Church*, 1843; Mackelvie, *Annals and Statistics of the United Presbyterian Church*, 1873.

UNITED PROVINCES. See HOLLAND.

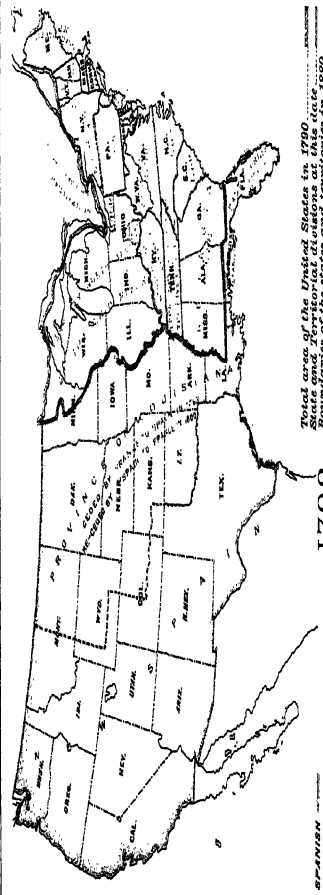

² The majority of this synod joined the Church of Scotland in 1839. The small minority which still retained the name joined the Original Seceders (see next note) in 1842, the resultant body assuming the designation of United Original Seceders. A small majority (twenty-seven ministers in all) of the Synod of United Original Seceders joined the Free Church in 1852. A synod of this name still exists, having under its jurisdiction four presbyteries, with twenty-nine charges (of which two are in Ireland).

³ A dissentient remnant (eight congregations) of the General Associate Synod united with the Constitutional Associate Presbytery in 1827, the resultant body being called the Associate Synod of Original Seceders.

¹ The passing of the Act was certainly unconstitutional; it was rescinded in 1734, "because not made according to former Acts."

I. COLONIZATION : 1607-1750.

Plate
VII.
Early
voyages
and
explora-
tions.

1. **T**HOUGH the voyages of the Cabots (1497-98) along the coast of North America were the ground on which the English finally adopted as a basis for their claims on that continent, no very effective steps were taken to reduce the continent to possession until after 1606. Martin Frobisher (1576) failed in an attempt to explore Labrador. Sir Humphrey Gilbert (1578) failed in a similar attempt on the continent; and in a second effort (1583) he was lost in a storm at sea on his return. In 1584 his half-brother Raleigh took up the work under commission from Queen Elizabeth. He sent two small vessels under Amidas and Barlow. They explored the south-central coast of what is now the United States, and returned with such flattering reports that the courtly Raleigh at once named the country Virginia, in honour of the queen, and sent out a colony. It was starved out in a year (1585). He sent another to the same place, Roanoke Island (1587), but it had disappeared when it was searched for three years after. Gosnold (1602) found a shorter route across the Atlantic, and spent a winter on an island off the present coast of Massachusetts; but his men refused to stay longer. These are the official records of English explorations up to 1606; but it is pretty certain that fishing and trading voyages, of which no record was kept, were more common than has been supposed, and that they kept alive a knowledge of the country.

London
and Ply-
mouth
Com-
panies.

2. In 1606 James I. formed two companies by a single charter. To one, the London Company, he granted the North-American coast between 34° and 38° N. lat.; to the other, the Plymouth Company, whose membership was more in the west of England, he granted the coast between 41° and 45° N. lat. The intervening coast, between lat. 38° and 41°, or between the Rappahannock and Hudson rivers, was to be common to both, but neither was to plant a settlement within 100 miles of a previous settlement of the other. Each was to be governed by a council appointed by the king, and these councils were to appoint colonial councils of thirteen, with really absolute powers. Neither company did much in colonization: the London Company gave up its charter in 1624, and the Plymouth Company, after a complete change of constitution in 1620, surrendered its charter in 1635. But the London Company at least began the work of colonization, and the Plymouth Company parcelled out its grant to actual colonists. Above all, the charter of the two companies had granted the principle to which the colonists always appealed as the foundation of English colonization in North America, as the condition on which immigrants had entered it, irrevocable unless by mutual consent of crown and subjects: "Also we do, for us, our heirs and successors, declare by these presents that all and every the persons, being our subjects, which shall go and inhabit within the said colony and plantation, and every their children and posterity, which shall happen to be born within any of the limits thereof, shall have and enjoy all liberties, franchises, and immunities of free denizens and natural subjects within any of our other dominions, to all intents and purposes as if they had been abiding and born within this our realm of England, or in any other of our dominions."

3. The London Company was first in the field. A ship-load of the adventurers then swarming in London was sent

out under Christopher Newport. He found a fine river, which he named after the king, and on its banks, within the present State of Virginia, he planted the settlement of Jamestown¹ (13th May 1607). Misgovernment, dissension, mismanagement, and starvation were almost too much for the infant colony, and several times the colonists were on the point of giving it up and going home. Twelve years were required to put Virginia on a sound footing. By that time the liberal element in the London Company had got control of it, and granted the colonists a representative government. The year in which this house of burgesses met (1619) was the year in which African slaves were introduced into the colony from a Dutch vessel.

4. Separatists from the Church of England began the more northerly settlements. Driven from England, they found refuge in Holland. Thence returning for the moment to England, a company of 102 of them set sail for America in the "Mayflower," landing (December 21, 1620) at Plymouth, in the south-eastern part of the present State of Massachusetts. The rigours of a new and cold country, combined with poverty and the payment of interest at 45 per cent., made the early years of the Plymouth colony a desperate struggle for existence, but it survived. It had no special charter, but a licence from the Plymouth Company. Other little towns were founded to the north of this settlement, and in 1629 these were all embraced in a charter given by Charles I. to the Governor and Company of Massachusetts Bay. This was a Puritan venture, composed of men of higher social grade than the Plymouth Separatists, and was meant to furnish a refuge for those who dreaded the ecclesiastical policy of the crown. The next year the company took the bold step of transferring its organization to America, so as to be out of the immediate notice of the crown and its agents. Eleven vessels took more than a thousand colonists over, and the real colony of Massachusetts was begun.

5. The charter of the London Company was surrendered to the crown, as has been said, in 1624; and the king thereafter disposed of the territory which had been granted to it as he pleased. In 1632 the new colony of Maryland of Maryland was carved out of it for Lord Baltimore. In 1663 the territory to the south of the present State of Virginia was cut off from it and called Carolina, covering the present States of North and South Carolina and Georgia. In 1729 Carolina was divided into North and South Carolina; and in 1732 the last of the colonies, Georgia, was organized. Five distinct colonies were thus formed out of the original London Company's grant.

6. When the Plymouth Company finally surrendered its charter in 1635, it had made one ineffectual attempt at colonization (1607) near the mouth of the Kennebec river, in Maine, and one complete colony, Massachusetts Bay, had arisen within its territory. Another colony, that of Plymouth, existed by licence. Massachusetts settlers, without even a licence, were pouring into the vacant

¹ The former settlement of Jamestown is now in James City county, Va., about 32 miles from the mouth of the James river. It was at first the capital of the colony, but began to decline when Williamsburgh was made the capital. Its death-blow was received when it was burned in 1676, during Bacon's rebellion. It was not rebuilt, and has now almost disappeared. "Nothing remains but the ruins of a church tower covered with ivy, and some old tombstones. The river encroaches year by year, and the ground occupied by the original huts is already submerged."

of Connecticut and Rhode Island; of New Hampshire.

territory to the south of Massachusetts, there to form the colonies of Connecticut and Rhode Island, afterwards chartered by the crown, 1662 and 1663. A few fishing villages to the north of Massachusetts, established under the grant of John Mason, were the nucleus of the colony of New Hampshire. The present States of Vermont and Maine were not yet organized. Out of the original Plymouth Company's grant were thus formed the colonies of Massachusetts, Connecticut, Rhode Island, and New Hampshire. The name New England was commonly applied to the whole territory from the beginning, having been first used by Captain John Smith in 1614.

7. Nine of the "old thirteen" colonies are thus accounted for. The remaining four fell in the territory between the two main grants, which was to be common to both companies, but was in fact never appropriated by either. The Spaniard had settled contentedly far to the south; and the Frenchman, still bound by too many of the ancient ecclesiastical influences to contest supremacy with the Spaniard, had settled as far to the north as possible, in Canada. England had been so far released from ecclesiastical influences by the spread of the Reformation as to be prepared to contest supremacy with Spaniard, Frenchman, or any one else; but her lingering desires to avoid open conflict at any cheap rate had tended to fix her settlements on the very choicest part of the coast, in the middle latitudes,—a fact which was to colour the whole future history of the continent. The concurrent claims of the two English companies in the central zone seem to have deterred both of them from any attempt to interfere with the development of a colony there by the only other people of western Europe which was prepared to grasp at such an opportunity. The Dutch (1609) sent out Henry Hudson, an Englishman in their service, and he made the first close exploration of this central region. Dutch merchants thereupon set up a trading post at Manhadoes (the present city of New York), where a government under the Dutch West India Company was organized in 1621, when the Dutch states-general had granted the territory to it. The territory was named New Netherland, and the town at the mouth of the Hudson river New Amsterdam. Sweden sent a colony to Delaware Bay in 1638; but the attempt was never thoroughly backed, and in 1655 it was surrendered to the Dutch.

8. By the time of the Restoration in England, the northern and southern English colonies had developed so far that the existence of this alien element between them had come to be a recognized annoyance and danger. From the Hudson river to Maine, from the Savannah river to Delaware Bay, all was English. Roads had been roughly marked out; ships were sailing along the respective coasts as if at home; colonial governments were beginning to lean upon one another for support; but between the two was a territory which might at any moment turn to hostility. There was an evidently growing disposition in New England to attempt the conquest of it unaided. When England and Holland found themselves at war (1664), the opportunity arrived for a blow at Holland's colonial possessions. An English army and fleet under Colonel Nichols touched at Boston, and, proceeding thence to New Amsterdam, took possession of the whole central territory. It had been granted by the king to his brother, the duke of York, and the province and city were now named New York in honour of the new proprietor. The duke, the same year, granted a part of his territory to Berkeley and Carteret, and the new colony of New Jersey was the result. In 1681 the great parallelogram west of New Jersey was granted to Penn and called Pennsylvania. In the following year Penn bought from the duke of York the little piece of territory which remained united to Penn-

The Dutch settlements.

The colony of New York; of New Jersey; of Pennsylvania;

sylvania until the revolution, then becoming the State of Delaware. The central territory thus furnished four of the "old thirteen" colonies, New England four, and the southern portion five.

9. If there was any governing idea in the organization of the colonial governments, it was of the rudest kind; and in fact each was allowed to be so largely modified by circumstances that, with a general similarity, there was the widest possible divergence. A general division of the colonial governments is into charter, proprietary, and royal governments. The charter governments were Massachusetts, Connecticut, and Rhode Island. In these the colonial governments had charters from the crown, giving the people, or freemen, the right to choose their own governors and other magistrates, to make their own laws, and to interpret and enforce them. Only Connecticut and Rhode Island kept their charters intact. The Massachusetts charter was cancelled by the crown judges (1684) under a *quo warranto*; and in 1691 a new charter was granted. As it reserved to the crown the appointment of the governor, with an absolute veto on laws and after 1726 on the election of the speaker of the lower house, Massachusetts was thus taken out of the class of purely charter colonies and put into that of a semi-royal colony. The proprietary colonies were New Hampshire, New York, New Jersey, Pennsylvania (including Delaware), Maryland, Carolina, and Georgia. These were granted to proprietors, who, as inducements to settlers, granted governmental privileges almost as liberal as those of the charter colonies. Only Pennsylvania, Delaware, and Maryland remained proprietary colonies down to the revolution, and in these the governor had a charter right of veto on legislation. Virginia became a royal colony in 1620, and New York as soon as its proprietor became king; and other proprietors, becoming tired of continual quarrels with the colonists, gradually surrendered their grants to the crown. New Hampshire, New York, New Jersey, North and South Carolina, and Georgia had thus become royal colonies before the revolution. In the royal colonies, commonly called provinces, the governors were appointed by the crown, and had an absolute veto on legislation. There were thus at last three proprietary, seven royal, one semi-royal, and two charter colonies.

The proprietary colonies.

The royal colonies.

10. The two charter colonies were simple representative democracies, having the power to legislate without even a practical appeal to the crown, and having no royal governor or agent within their borders. Their systems were the high-water mark to which the desires and claims of the other colonies gradually approached. Massachusetts and the proprietary colonies were very nearly on a level with them; and the royal or proprietary governor's veto power was rather an annoyance than a fundamental difference. But in all the colonies representative governments had forced their way, and had very early taken a bicameral shape. In the charter colonies and Massachusetts the lower house was chosen by the towns and the upper house from the people at large, and the two houses made up the "assembly." In Pennsylvania and Delaware there was but one house. In the royal colonies and in Maryland the lower house alone was elected by the people; the upper house, or council, was chosen by the crown through the governor; and the assent of all three elements was essential to legislation. In the final revolution the charter colonies did not change their governments at all; they already had what they wanted. The revolution was consummated in the other colonies by the assumption of power by the lower or popular house, usually known as the "assembly," the governor or council, or both, being ousted.

Representative systems.

11. All these governmental organizations take a pro-

Town
and
parish.

minent place in American history, and had a strong influence on the ultimate development of the United States; and yet they touched the life of the people at comparatively few points. A more marked and important distinction is in the local organizations of the northern and southern colonies. All the southern colonies began as proprietary governments. Settlers went there as individuals connected only with the colony. To the individual the colony was the great political factor; his only other connexion was with his parish, to which the colony allowed few political functions; and, where political power touched him at all, it was through the colony. In time it became necessary to allow political powers to the parish or county, but they were really more judicial than political. "The southern county was a modified English shire, with the towns left out." The whole tendency shows the character of the immigration in this part of the country, from English districts outside of the influence of the towns.

The
town
system.

12. In New England local organization was quite different. A good example is the town of Dorchester. Organized (March 20, 1630) in Plymouth, England, when its people were on the point of embarkation for America, it took the shape of a distinct town and church before they went on shipboard. Its civil and ecclesiastical organization were complete before they landed in Massachusetts Bay and came under the jurisdiction of a chartered company. Its people governed themselves, in their town government, in all but a few points, in which the colony asserted superiority. As the colony's claims increased, the town's dissatisfaction increased. In 1635 the town migrated in a body, with its civil and ecclesiastical organization still intact, into the vacant territory of Connecticut, and there became the town of Windsor. Here, uniting with other towns, which had migrated in a similar fashion, it formed the new Commonwealth of Connecticut, in which the local liberty of the towns was fully secured in the frame of government. Rhode Island was formed in the same way, by separate towns; Vermont afterwards in the same way; and the towns of the parent colony of Massachusetts learned to claim a larger liberty than had been possible at first. Thus, all through New England, the local town organizations came to monopolize almost all ordinary governmental powers; and the counties to which the towns belonged were judicial, not political, units, marking merely the jurisdiction of the sheriff. In the annual town meetings, and in special meetings from time to time, the freemen exercised without any formal grant the powers of self-taxation, of expenditure of taxation, of trial by jury, and of a complete local government. Further, the lower houses of their colonial legislatures were made up of generally equal representations from the towns, while the upper houses were chosen from the colony at large. In this was the germ of the subsequent development of the United States senate, in which the States are equally represented, and of the house of representatives, representing the people numerically (§§ 104, 105, 109, 110).

The
middle
colonies.

13. The two opposite systems of the north and south found a field for conflict in the organization of the central territory after its acquisition (§ 8). The crown agents were strongly disposed to follow the more centralized system of the southern colonies, though Penn, having organized counties and restricted his legislature to a single house, based it on the counties. In New York and New Jersey the Dutch system of "patroonships" had left a simulacrum of local independence, and a stronger tendency in the same direction came in through immigration from New England. To encourage this immigration, the New Jersey proprietors gave town powers to many of them; and some of the New Jersey towns were merely transplanted New England towns. But the middle colonies

never arrived at any distinct system; at the best, their system was a conglomerate. Much the same result has been reached in the new Western States, organized under the care of the Federal Government, where the New England immigration has brought with it a demand for local self-government which has resulted in a compromise between the two systems of town units and county units.

14. Ecclesiastical divisions were at first as strong as civil diversities. The New England colonies were Congregational, and these churches were established and supported by law, except in Rhode Island, where the Baptists were numerically superior. In the royal colonies generally there was a steady disposition to establish the Church of England, and it was more or less successful. In language there were striking dissimilarities, due to a most heterogeneous immigration. It was said that every language of Europe could be found in the colony of Pennsylvania. But, after all, this diversity had no indications of persistence; the immigration in each case had been too small to support itself. Very little of the wonderful increase of American population between 1607 and 1750 was due to immigration; most of it had come from natural increase. After the first outflow from Old to New England, in 1630-31, emigration was checked at first by the changing circumstances of the struggle between the people and the king, and, when the struggle was over, by the better-known difficulties of life in the colonies. Franklin, in 1751, when he estimated that there were "near a million English souls" in the colonies, thought that scarce eighty thousand had been brought over by sea. No matter how diverse the small immigration might have been on its arrival, there was a steady pressure on its descendants to turn them into Englishmen; and it was very successful. When Whitefield, the revivalist, visited America about 1740, he found the population sufficiently homogeneous for his preaching to take effect, all the way from Georgia to New England. The same tendency shows itself in the complete freedom of intercolonial migration. Men went from one colony to another, or held estates, or took inheritances in different colonies, without the slightest notion that they were under any essentially diverse political conditions. The whole coast, from Nova Scotia to the Spanish possessions in Florida, was one in all essential circumstances; and there was only the need of some sudden shock to crystallize it into a real political unity. Hardly anything in history is more impressive than this mustering of Englishmen on the Atlantic coast of North America, their organization of natural and simple governments, and their preparations for the final march of 3000 miles westward, unless it be the utter ignorance of the home Government and people that any such process was going on.

15. This ignorance had one singular effect in completing the difference between the new and the old country. An odd belief that European plants and animals degenerated in size and quality on transplantation to the western continent was persistent at the time even among learned men in Europe, and Jefferson felt bound to take great pains to combat it so late as the end of the 18th century. That passage in Thackeray's *Virginians*, where the head of the elder Virginian branch of the family returns to England, to be treated with contempt and indifference by the younger branch which had remained at home, indicates the state of mind among the influential classes in England which bent them against any admission of Americans to the honours or privileges of the English higher classes. A few titles were given; entails were maintained in the southern colonies; but there were no such systematic efforts as are necessary to maintain an aristocratic class. This may have been gratifying to the ruling class in England; but it was in reality an unconsciously system-

Ecclesi-
astical
systems.

Immigra-
tion.

Demo-
cracy.

atic effort to develop democracy in the English colonies in North America. In combination with the free representative institutions which had taken root there, it was very successful, and, when the final struggle between the English ruling class and the colonists took shape, the former had singularly few friends or allies in the colonies. What the results might have been if efforts had been made to build up a titled class in the colonies, with entailed revenues and hereditary privileges in the upper houses of the colonial legislatures, is not easy to imagine; but the prejudices of the privileged classes at home eliminated this factor from the problem. Every influence conduced to make the American commonwealths representative democracies; and the reservation of crown influence in the functions of the governors or the appointment of the council was merely a dam which was sure to be broken down as development increased.

Social
con-
ditions.

16. Social circumstances had all the features of life in a new country, aggravated by the difficulties of inter-communication at that time. In the southern and middle colonies there was a rude abundance, so that, however much the want of luxuries might be felt, there was no lack of the necessities of life. The growth of tobacco, indigo, and rice in the southern colonies was so large a source of wealth that luxury in that part of the country had taken a more pronounced form than in the others. The southern planter, trained in English schools and universities and admitted to the English bar, was more like an English gentleman in a condition of temporary retirement than an American colonist. The settler of the middle colonies was the ordinary agriculturist. The hardships of colonial life were the special lot of the New England colonist. For some reason—perhaps because the forests retained the snow on the ground—the New England winters were more severe than they are now. The rudely built house, with its enormous chimney attracting draughts of outer air from every point, was a poor protection against the cold. Travel, difficult enough at the best, became impossible in winter, unless the snow rose so high as to blot out the roads and permit the traveller to drive his sledge across country. Medical and surgical attendance was scarce in summer, and hardly dreamed of in winter. The religious feeling of the people was against amusements of all kinds, except going to funerals, an occasional dinner, and the restricted enjoyments of courtship. It was a point of honour or of religious feeling to exclude luxury from church equipment: stoves were not known in Connecticut churches until the beginning of this century, and yet newborn infants were taken to church for baptism in the bitterest weather.¹

Educa-
tion.

17. Wealth in the southern colonies was sufficient to give the better classes there an education of a very high order; and they in turn, by virtue of their political and social leadership, imparted something of their acquisitions to those below them. In the middle colonies commercial pursuits and those interests which go to make men of affairs had something of the same influence on special classes. In New England education was more general, even though it had no such advantages for special classes as at the south. The first immigration into New England contained an unusually large proportion of English university men, particularly among the ministers. These

¹ An extract from a New England diary of 1716 will give some notion of social circumstances at that comparatively late period. "Lord's Day, Jan'y. 15. An extraordinary cold Storm of wind and Snow. Blows much as coming home at Noon and so holds on. Bread was frozen at the Lord's table; Mr Pemberton administered. Came not out to afternoon exercise. Though 'twas so cold, yet John Tuckerman was baptised. At six a-clock my ink freezes so that I can hardly write by a good fire in my wife's chamber. Yet was very comfortable at meeting. *Laus Deo.*"

fixed the mould into which their descendants have been run, and New England's influence in the United States has been due largely to them. The town system added to their influence. Owing to it the ebbing and flowing of population through New England was not blind or unorganized. Every little town was a skeleton battalion, to be filled up by subsequent increase and immigration; and the ministers and other professional men made a multitude of successors for themselves, with all their own ideas. Considering the execrable quality of school and college instruction in New England, as elsewhere at the time, it is very remarkable that, as the original supply of university-bred leaders died off, there was a full crop of American-bred men quite prepared to take their places and carry on their work. Here were Harvard and Yale, the two leading colleges of the country, which in 1760 had six:—Harvard College, in Massachusetts (founded in 1636); William and Mary College, in Virginia (1692); Yale College, in Connecticut (1700); Princeton College, in New Jersey (1746); Pennsylvania University (1749); and King's, now Columbia, College, in New York (1754).

18. Shipwrights had been sent to Virginia at an early Com-date; but shipbuilding never made great head in the merce. southern colonies, in spite of the fact that they had all the materials for it in abundance. At a later period ships were built, and it was not uncommon for planters to have their private docks on their own plantations, where their ships were freighted for Europe. But such building was individual: each planter built only for himself. The first vessel built by Europeans in this part of the continent was constructed by Adrian Block at New Amsterdam (1614). Many small vessels were built at the mouth of the Hudson river under Dutch and English domination, but New York's commercial supremacy did not fairly begin until after the revolution. Perhaps the hardships of life in New England made its people prefer water to land; at any rate they took to shipbuilding early and carried it on diligently and successfully. Plymouth built a little vessel before the settlement was five years old, and Massachusetts another, the "Blessing of the Bay" (1631). Before 1650 New England vessels had begun the general foreign trade, from port to port, which combined exportation with a foreign coasting trade and mercantile business, the form in which New England commercial enterprise was to show itself most strongly. Before 1724 English ship-carpenters complained of the competition of the Americans, and in 1760 the colonies were building new ships at the rate of about 20,000 tons a year, most of them being sold in England.

19. The earliest manufactures in the colonies were natur- Manu-
ally those of the simplest kind, the products of sawmills, factures
grist-mills, and tanneries, and home-made cloth. The and
search for ores, however, had been a prime cause of immi- mining.
gration with many of the settlers, and they turned almost
at once to mining and metallurgy. Most of their efforts
failed, in spite of "premiums," bounties, and monopolies
for terms of years granted by the colonial legislatures.
To this the production of iron was an exception. It was
produced, from the beginning of the 18th century, in
western Massachusetts and Connecticut, in eastern New
York, in northern New Jersey, and in eastern Pennsyl-
vania. All these districts were about on a level, until the
adaptation of the furnaces to the use of anthracite coal
drove the New England and New York districts, which
had depended on wood as fuel, almost out of competition
(\$ 210). Until that time iron production was a leading
New England industry. Not only were the various pro-
ducts of iron exported largely; the manufacture of nails,
and of other articles which could be made by an industrious
agricultural population in winter and stormy weather, was

a "home industry" on which New Englanders depended for much of their support.

The English colonial system.

20. The colonial system of England differed in no respect from that of other European nations of the time; probably none of them could have conceived any other as possible. The colonies were to be depôts for the distribution of home products on a new soil; whenever they assumed any other functions they were to be checked. The attempts of the Americans to engage in commerce with other nations, their shipbuilding, and their growing manufactures were, in appearance, deductions from the general market of English producers, and the home Government felt itself bound to interfere. Virginia claimed, by charter-right, the power to trade freely with foreign nations; and Virginia was notoriously on the side of the Stuarts against the Parliament. In 1651 parliament passed the Navigation Act, forbidding the carrying of colonial produce to England unless in English or colonial vessels, with an English captain and crew. By the Act of 1661, the reach of the system was extended. Sugar, tobacco, indigo, and other "enumerated articles," grown or manufactured in the colonies, were not to be shipped to any country but England. All that was necessary to make this part of the work complete was to add to the "enumerated articles," from time to time, any which should become important colonial products. The cap-stone was placed on the system in 1663, when the exportation of European products to the colonies was forbidden unless in vessels owned and loaded as in the preceding Acts and loaded in England. Virginia's commerce withered at once under the enforcement of the system. New England, allowed to evade the system by Cromwell for political reasons, continued to evade it thereafter by smuggling and bold seamanship.

Restrictive laws.

21. In 1699, on complaint of English manufacturers that the colonists were cutting them out of their foreign wool markets, parliament enacted that no wool or woollen manufactures should be shipped from any of the colonies, under penalty of forfeiture of ship and cargo. This was the first fruits of the appointment of the Board of Trade and Plantations three years before. From this time until the revolution, this body was never idle; but, as its work was almost confined to schemes for checking or destroying the trade and manufactures of the plantations, it cannot be said to have done them any great service. It was continually spurring on colonial governors to turn their people to the production of naval stores, or to any occupation which would divert them from manufactures; and the governors, between fear of the legislatures which paid their salaries and of the Board which was watching them narrowly, had evidently no easy position. At intervals the Board heard the complaints of English manufacturers, and framed remedial bills for parliament. From 1718 the manufacture of iron was considered particularly obnoxious; and, so late as 1766, Pitt himself asserted the right and duty of parliament to "bind the trade and confine the manufactures" of the colonies, and to do all but tax them without representation. In 1719 parliament passed its first prohibition of iron manufactures in the colonies; and in 1750 it forbade under penalties the maintaining of iron-mills, 'slitting or rolling mills, plating-forges, and steel-furnaces in the colonies. At the same time, but as a favour to English manufacturers, it allowed the importation of American bar-iron into England, as it was cheaper and better than the Swedish. Before this, in 1731, parliament had forbidden the manufacture or exportation of hats in or from the colonies, and even their transportation from one colony to another. All these Acts, and others of a kindred nature, were persistently evaded or defied; but the constant training in this direction was not a good one for the

maintenance of the connexion between the colonies and the mother country, after the interested classes in the colonies should become numerous and their interests large. Unluckily for the connexion, the arrival at this point was just the time when the attempt was first made to enforce the Acts with vigour (§ 38).

22. English imports from the North-American colonies The American market. amounted to £395,000 in 1700, £574,000 in 1730, and £761,000 in 1760; the exports to the colonies in the same years were £344,000, £537,000, and £2,612,000. In spite of parliamentary exactions and interferences, a great and entirely new market had been opened to English trade. The difference between the year 1606, when there was not an English settler on the North American continent, and 1760, when there were a million and a half with a great and growing commerce, is remarkable. It is still more remarkable when one considers that this population was already nearly one-fourth of that of England and Wales. Its growth, however, steadily increased the difficulties of maintaining the English system of control, which consisted mainly in the interference of the governors with legislation proposed by the assemblies. As the numbers and material interests of the subjects increased, the necessities for governmental interference increased with them, and yet the power of the subjects to coerce the governors increased as well. Only time was needed to bring the divergence to a point where change of policy must have disruption as its only alternative.

23. Merely material prosperity, the development of Religious wealth and comfort, was very far from the whole work of freedom. the colonies. In spite of attempts in almost every colony to establish some form of religious belief on a government foundation, religious freedom had really come to prevail to an extent very uncommon elsewhere at the time. Even in New England, where the theory of the state as an isolated opportunity for the practice of a particular form of worship had been held most strongly, persecution was directed chiefly against the Quakers, and that mainly on semi-political grounds, because of their determination to annoy congregations in their worship or to outrage some feeling of propriety. As soon as it came to be realized that the easiest method to deprive them of the power of annoyance was to ignore them, that method was adopted; indeed, two of the New England colonies took hardly any other method from the beginning.

24. In political work the colonies had been very suc- Political cessful. They had built up thirteen distinct political freedom. units, representative democracies so simple and natural in their political structure that time has hardly changed the essential nature of the American State governments. In so doing, the Americans were really laying the foundations of the future national structure, for there is hardly a successful feature in the present national government which was not derived or directly copied from the original colonial growths; while the absolutely new features, such as the electoral system (§ 119), introduced into the national system by way of experiment, have almost as generally proved failures, and have been diverted from their original purposes or have become obsolete.

II. THE STRUGGLE FOR EXPANSION: 1750-63.

25. The English settlements along the Atlantic had covered the narrow strip of coast territory quite thoroughly before it was possible to think of expansion westward. Since about 1605 Canada had been undisputedly in the hands of the French. Their traders and missionaries had entered the present western United States; Marquette and Joliet (1673) and La Salle (1682) had explored the upper Mississippi river, and others, following their track, had explored most of the Mississippi valley and had built forts

The French in Canada and the west.

in various parts of it. About 1700 the French opened ground at the mouth of the Mississippi; D'Iberville (1702) founded Mobile and the French Mississippi Company (1718) founded the city of New Orleans. Consistent design, foiled at last only by failure of material, marks the proceedings of the French commanders in America for the next thirty years. New Orleans and Quebec were the extremities of a line of well-placed forts which were to secure the whole Mississippi valley, and to confine the English settlements for ever to the strip of land along the coast bounded on the west by the Appalachian or Alleghany range of mountains, which is parallel to the coast and has but one important break in its barrier, the opening through which the Hudson river flows. The practical genius of the French plans is shown by the fact that so many of these old forts have since become the sites of great and flourishing western cities: Natchez, Vincennes, Peoria, Fort Wayne, Toledo, Detroit, Ogdensburg, and Montreal either are built on or are so near to the old forts as to testify to the skill and foresight against which the English colonies had to contend. To this whole territory, extending from the mouth of the Mississippi to that of the St Lawrence, covering even the western part of the present State of New York, the name of New France was given. The English possessions, extending in hardly any place more than a hundred miles from the ocean, except where the Dutch had long ago planted the outpost of Fort Orange, or Albany, on the upper Hudson, were generally restricted to the immediate neighbourhood of the coast, to which the early population had naturally clung as its base of supplies.

Weak-
ness of
the
French
system.

26. The French difficulties were even greater than those of the English. The French people had never had that love of emigration which had given the English colonies their first great impetus. Even where the French settled they showed more of a disposition to coalesce with the native population than to form a homogeneous people. The French were commonly far stronger with the Indians than were the English; but, at the end of a hundred and fifty years, when the English colonists numbered a million and a quarter, all animated by the same political purposes, the population of all New France was only about 100,000, and it is doubtful whether there were 7500 in the whole Mississippi valley. The whole French system, wisely as it was designed, was subject to constant and fatal interference from a corrupt court. Its own organization was hampered by attempts to introduce the feudal features of home social life. A way was thus opened to exactions from every agent of the court, to which the people submitted with hereditary patience, but which were fatal to all healthy development. Perhaps worst of all was the natural and inevitable formation of the French line of claims. Trending westward from Quebec to meet the northward line of forts from New Orleans, it was bent at the junction of the two parts, about Detroit, and its most important part lay right athwart the path of advancing English migration. The English wave was thus to strike the weaker French line in flank and at its weakest point, so that the final issue could not in any event have been doubtful. The French and Indian war probably only hastened the result.

Inter-
colonial
wars.

27. There had been wars between the French and the English colonies since the accession of William and Mary, mostly accessory to wars between the mother countries. The colonies had taken part in the wars ended by the peace of Ryswick (1697), the peace of Utrecht (1713), and the peace of Aix-la-Chapelle (1748). The alliance of the French and Indians made all these struggles wretched experiences for the English. The province of Canada became a prison-pen, where captives were held to ran-

som or adopted into savage tribes. Outlying settlements were broken up, or forced to expend a large part of their energy in watchful self-defence; and it required all the persistence of the English colonies to continue their steady forward movement. Nevertheless they even undertook offensive operations. They captured Port Royal in 1690, but it was given up to the French in 1697. They captured it again in 1710, and this time it was kept, with most of Acadia, which was now to be known as Nova Scotia. In 1745 the colonies took the strongest French fortress, Louisburgh, on Cape Breton Island, with very little assistance from the home Government. Their land expeditions against Montreal and Quebec were unsuccessful, the reason for failure being usually defective transport.

28. In the treaties which closed these wars, the interests of the colonies met with little consideration. The most notable instance of this was the 12th article of the treaty of Utrecht, by which an English company was secured the exclusive right to carry African slaves into American ports. Originally meant to obtain the Spanish trade in negroes, the company had influence enough to commit the crown to a steady support of the African slave-trade in its own colonies. Again and again the English legislatures in North America attempted to stop the slave-trade, and were prevented by the royal veto. This will serve to explain a passage in Jefferson's first draft of the American Declaration of Independence, as follows:—"He [the king] has waged cruel war against human nature itself. . . . Determined to keep open a market where men should be bought and sold, he has prostituted his negative for suppressing every legislative attempt to prohibit or to restrain this execrable commerce."

29. All parties seem to have felt that the peace of Aix-la-Chapelle was but a truce at the best; and the French court seems to have come at last to some comprehension of its extensive opportunities and duties in North America. With its tardy sympathy, its agents on the new continent began the erection of barriers against the great wave of English westward migration which was just appearing over the crest of the Alleghanies. It was too late, however, for the English colonies were really able to sustain themselves against the French colonies and court together. Their surveyors (1747) had crossed the crests of the mountains, and had brought back appetizing accounts of the quality of the lands which lay beyond. The Ohio Company (1749), formed partly of Virginian speculators and partly of Englishmen, had obtained a grant of 500,000 acres of land in the western part of Pennsylvania (then supposed to be a part of Virginia), with a monopoly of the Indian trade. As the grant was completely on the western side of the Alleghanies, and was the first English intrusion into the Ohio valley, it behoved the French to meet the step with prompt action. Their agents traversed the Ohio country, making treaties with the Indians and burying lead plates inscribed with the lilies of France and a statement of the French claims. The erection of the Ohio Company's first fort (1752) brought on the crisis. The main line of French forts was too far away to be any check upon it. The French leaders therefore began to push a branch line eastward into the disputed territory. Their first work (1753) was put up at Presque Isle (now Erie), about 100 miles north of the Ohio Company's fort. The citadel of the disputed territory had been begun on the spot where Pittsburgh now stands, where the Allegheny and Monongahela unite to form the Ohio river. Governor Dinwiddie, of Virginia, had obtained the right to erect the fort by treaty with the Indians. From Presque Isle the French began running a line of forts south, through the present "oil district" of Pennsylvania, towards the headquarters of the English.

The Ohio
Company.

30. Washington was then a land-surveyor, barely of age; but he was the agent whom Dinwiddie selected to carry an ultimatum to the French at Presque Isle. After a perilous winter passage through the wilderness, he found that the French had no intention of evacuating their positions, and returned. Virginia at once (January 1754) voted money and men to maintain the western claims of the colonies; and Washington was sent with 400 provincial troops to secure the half-built fort at the head of the Ohio. The French were also pushing for that place. They won in the race, drove away the English workmen, and finished Fort Du Quesne, named after their governor. Washington, compelled to stop and fortify his position, won the first skirmish of the war with the French advanced guard, but was forced to surrender on terms (July 4, 1754). The usual incidents of a general Indian warfare followed for the rest of the year.

The French and Indian war.
31. Both Governments began to ship regular troops to America, though there was no formal declaration of war until 1756. The year 1755 was marked by the surprise and defeat of Braddock, a gallant and opinionated British officer who commanded an expedition against Fort Du Quesne, by the complete conquest of Nova Scotia, and by the defeat of the French, under their principal officer, Dieskau, at Lake George, in New York, by a force of provincial troops under Sir William Johnson. In 1756 the greatest of French Canadian governors, Montcalm, arrived; and the tide of war went steadily against the English. The officers sent out by the home Government were incompetent, and they generally declined to draw on the colonists for advice. Montcalm found them an easy prey; and his lines were steadily maintained at the point where they had been when Washington surrendered at Fort Necessity. Pitt's entrance to the Newcastle ministry (June 1757) changed all this. For the first time the colonies found a man who showed a sympathy with them and a willingness to use them. Their legislatures were summoned into counsel as to the conduct of the war; and their alacrity in response was an augury of a change in its fortune. Incompetent officers were weeded out, with little regard to family or court influence. The whole force of the colonies was gathered up, and in 1758 was launched at the French. All western New York was cleared of the enemy at a blow; Fort Du Quesne was taken and renamed Fort Pitt; Louisburgh, which had been restored to France at Aix-la-Chapelle, was again taken; and the only failure of the year was the dreadful butchery of the English in assaulting the walls of Ticonderoga. Louisburgh made an excellent point of attack against Quebec, and Montcalm was forced to draw off nearly all his troops elsewhere for the defence of his principal post. The year 1759 was therefore begun by the capture of Ticonderoga and almost all the French posts within the present United States, and was crowned by Wolfe's capture of the towering walls of Quebec. In 1760, while George II. lay dying, the conquest of Canada was completed, and the dream of a great French empire in North America disappeared for ever.

Peace of Paris.
32. The war continued through the first three years of George III., and the colonies took part in the capture of Havana after Spain had entered the struggle as an ally of France. The peace of Paris, which put an end to the war, restored Havana to Spain, in exchange for Florida, which now became English. France retired from North America, giving to Spain all her claims west of the Mississippi and that small portion east of the Mississippi which surrounds New Orleans, and to England the remainder of the continent east of the Mississippi. Spain retained for her territory the name of Louisiana, originally given by the French. The rest of the continent was now "the English colonies of North America."

33. It is evident now that the French and Indian war was the prelude to the American revolution. It trained the officers and men for the final struggle. It released the colonies from the pressure of the French in Canada so suddenly that the consciousness of their own strength came at the same instant with the removal of the ancient barrier to it. It united the colonies for the first time; few things are more significant of the development of the colonies than the outburst of plans for colonial union between 1748 and 1755, the most promising, though it finally failed, being that of Franklin (1754) at the Albany conference of Indian commissioners from the various colonies. The practical union of the colonies, however, was so evident that it might have been foreseen that they would now unite instinctively against any common enemy, even the mother country.

34. The war, too, while it obtained its main object in the view of the colonies—an unlimited western expansion,—brought the seeds of enmity between them and the crown. The claims of the English on the continent, as has been said, were based on the voyages of the Cabots. Under them the crown had granted in the charters of Massachusetts, Connecticut, Virginia, North and South Carolina, and Georgia a western extension at first to the Pacific Ocean and finally to the Mississippi. This was what the colonies had fought for; and yet at the end of the war (1763) a royal proclamation was issued forbidding present land sales west of the Alleghanies and practically reserving the conquered territory as a crown domain. In this, if in nothing else, lay the seeds of the coming revolution, as it afterwards almost disrupted the rising Union. The war had welded the thirteen colonies into one people, though they hardly dreamed of it yet; they had an underlying consciousness that this western territory belonged to the new people, not to the crown or to the separate colonies which had charter claims to it; and they would have resisted the claims of the crown as promptly as they afterwards resisted the claims of the individual colonies. The con- quered territory.

35. Finally, the war broke the feeling of dependence on the mother country. Poorly armed, equipped, and disciplined, the colonial or "provincial" troops had certainly shown fighting qualities of no mean order. Colonists would not have been disposed, under any circumstances, to underrate the military qualities of their own men, but their self-glorification found a larger material because of the frequently poor quality of the officers who were sent through family and court influence to represent Great Britain in the colonies. The bitter words in which Junius refers to British military organization in after years were certainly even more applicable in 1750; and the incompetency of many of the British officers is almost incomprehensible. Its effects were increased by an utter indifference to the advice of colonial leaders which, in a new and unknown country, was certain to place British soldiers again and again in positions where they appeared to great disadvantage alongside of their colonial allies or rivals. The provincial who had stood his ground, firing from behind trees and stumps, while the regulars ran past him in headlong retreat, came home with a sense of his own innate superiority which was sure to bring its results. Braddock's defeat was the prologue to Bunker Hill. The results were strengthened by the fact that most of the war was fought either in New England, the most democratic of the colonies, or by New England men. Their leaders had always been sought for by annual popular elections and re-elections, the promotion of approved men, and the retention of men of poorer quality in lower grades of office. To them the aristocratic influences which gave place and power to such men as Loudoun and "Mrs Nabbycrombie" were simply ridiculous, and marked only an essential

difference between themselves and their English brethren which was to the disadvantage of the latter, even though it occasionally evolved a man like Howe or Pitt. Taking all the influences together, it is plain that the French and Indian war not only brought into being a tangible union of the colonies, but broke many of the cords which had held the colonies to the mother country.

III. THE STRUGGLE FOR UNION: 1763-75.

36. It is generally believed that the abandonment of North America by France was the result of profound policy,—that she foresaw that her retirement would be followed by the independence of the English colonies, and that Great Britain's temporary aggrandizement would result in a more profound abasement. Vergennes and Choiseul both stated the case in just this way in 1763; and yet it may be doubted whether this was not rather an excuse for yielding to necessity than a political motive. At all events, it is certain that the peace, even with its release of the colonies from French pressure, was not enough to secure colonial union. For this it was necessary that the home Government should go on and release the colonists from their controlling feeling that they were rather Englishmen than Americans.

English sympathies of the colonists

37. This feeling was not an easy one to eradicate, for it was based in blood, training, and sympathies of every nature. It would not have been easy to distinguish the American from the Englishman; it would, indeed, have been less easy than now, when the full effects of a great stream of immigration have begun to appear. American portraits of the time show typical English faces. Wherever life was relieved of the privations involved in colonial struggle, the person at once reverted to the type which was then the result of corresponding conditions in England. The traditions of American officers were English; their methods were English; even the attitude which they took towards the private soldiers of their armies was that which was characteristic of the English officer of the time. In the South the men who led and formed public opinion had almost all been trained in England and were ingrained with English sympathies and even prejudices. In the North the acute general intellect had long ago settled upon the "common rights of Englishmen" as the bulwark behind which they could best resist any attempt on their liberties. The pride of the colonists in their position as Englishmen found a medium of expression in enthusiasm for "the young king"; and it would be hard to imagine a more loyal appendage of the crown than its English colonies in North America in 1760.

Change of English policy.

38. Unfortunately, the peace of Paris did not result merely in freeing the colonies from dependence on the mother country; it had the more important effect of freeing the mother country from fear of France, and of thus encouraging it to open a controversy with the colonies which had not been ventured on before. Quebec had hardly fallen and given the home Government promise of success when the work was begun (1761). The Board of Trade began to revive those regulations of colonial trade which had been practically obsolete in New England; and its customs officers applied to the Massachusetts courts for "writs of assistance" to enable them to enforce the regulations. Instant resistance was offered to the attempt to burden the colonies with these writs, which governed all men, were returnable nowhere, gave the officers absolute power, and opened every man's house and property to their entrance. The argument of the crown advocates based the power of issuing such writs on parliament's extension of the English revenue system to the colonies, backed by a statute of Charles II. permitting writs of assistance; to refuse to grant the writs was therefore to impeach the

power of parliament to legislate for the colonies. The counter-argument of James Otis was the key-note of the revolution. It declared in terms that no Act of Parliament could establish such a writ, that it would be a nullity even if it were expressed in the very terms which the customs officers claimed, and that "an Act of Parliament against the constitution was void."

39. Perhaps Otis meant by "the constitution" merely the fundamental relations between the mother country and the colonies, for this claim was the first step on the way to the final irreconcilable difference as to these relations. The English theory of the connexion had been completely put into shape by 1760, with very little objection from the colonists, whose attention had not yet been strongly drawn to the subject. It held that even the two charter colonies, and *a fortiori* still more such a royal province as New York, were merely corporations, erected by the king, but subject to all the English laws relating to such corporations. The king was their visitor, to inquire into and correct their misbehaviours; his courts, on *quo warranto*, could dissolve them; and parliament had the same omnipotent power over them which it had over any other civil corporation,—to check, amend, punish, or dissolve them. These propositions must have seemed unquestionable to the English legal mind in 1763. Their weak point, the assumption that parliament had power to control a corporation *extra quatuor maria*, had been covered by a new development of the English theory during the century. Parliament, originally a merely English body, had grown in its powers and claims until now the common use of the phrase "imperial parliament" connoted claims to which the "four seas" were no longer a limitation, in law or fact. Parliament was to give the law to the whole empire. Hitherto this had been developed as a purely legal theory; it was now first attempted to be put into practice when the enforcement of the Navigation Acts was begun in 1761. The first objections offered by the colonists were easily shown to be illogical and inconsistent with this legal theory of the relations between the home country and the colonies, but this only drove the colonists higher, step by step, in their objections,—from objections to taxation by parliament into objections to legislation by parliament,—until they had developed, about 1775, a theory of their own, logical enough in itself, but so inconsistent with the English theory that war was the consequence of their collision.

40. Passing over the intermediate steps, the form which the colonial theory finally took amounted to this. The introduction of the idea of an "imperial parliament" was itself a revolution, which could not bind the colonists, or change the conditions under which they had settled the new country. Their relations, originally and properly, had been with the crown alone, and they had had nothing to do with parliament. The crown had seen fit to constitute new dominions for itself beyond the seas, with forms of government which were irrevocable compacts between it and the people whom it had thus induced to settle the new territory, and not mere civil corporations. It would follow, then, that the king was no longer king merely of Great Britain and Ireland; he had at least thirteen kingdoms beyond seas, and a parliament in each of them. For the British parliament to interfere with the special concerns of Massachusetts was as flagrant a wrong as it would have been for the parliament of Massachusetts to interfere with the affairs of Great Britain; and Massachusetts had a right to expect her king to protect her from such a wrong. The subject of Massachusetts knew the king only as king of Massachusetts, and the parliament of Great Britain not at all. It needed many years of successful but suicidal logic on the part of their opponents to

The English theory of colonial rights.

The colonists' theory.

force the Americans to this point; they even continued to petition parliament until 1774; but after that time they were no further inconsistent, and held that the king was the only bond of union between the parts of the empire. When he wanted money from his American dominions, he was to get it, as he had always got it, by applying to the assembly of the colony, through the governor, for a grant. In the new seats of the race, as in the old, an Englishman was to be taxed only by his own representatives. In other words, each of the English colonies claimed, in its own field and for its own citizens, the exact principles of "English liberty" which had been established in England as the relations of the English subject to the crown. Each colony was to be governed by its own laws, just as in Jersey and Guernsey, in Scotland before the Union, or in Hanover in 1763, with appeal to the king in council, not to English courts or to the House of Lords. For the British parliament, or still more the British citizen, to talk of "our sovereignty" over the colonies was a derogation from the king's sovereignty, the only sovereignty which the colonies knew. "I am quite sick of 'our sovereignty,'" wrote Franklin in 1769. The case of the colonies was evidently that of Ireland also; and Franklin notes the fact that several members of colonial assemblies had been admitted to the privileges of the Irish parliament, on the ground that they were members of "American parliaments." To this statement of their case the Americans adhered with progressive closeness from 1763 until the end. In their final Declaration of Independence it will be found that it is a declaration of their independence of the king only; they do not then admit that the British parliament had ever had any authority over them; and that body is only mentioned in one place, in one of the counts of the indictment of the king, for having given his assent to certain "acts of pretended legislation," passed by "a jurisdiction foreign to our constitutions and unacknowledged by our laws," that is to say, by the British parliament.

Possible
compro-
mises.

41. Two irreconcilable theories were thus presented. Between them were two courses, either of which the colonies were willing to accept. Under their theory there was no "imperial parliament." They were willing to have one constituted, even if it were only a development of the British parliament through admission of colonial representatives; but the time for this passed before the parties could debate it. On the other hand, the colonies were willing to abandon to the wealthier British parliament, which sustained so much larger a proportion of the cost of the standing army and navy, the privilege of regulating external trade for the general good. So late as 1774 the Continental Congress, while maintaining the sole right of the colonial assemblies to levy internal taxation and make local laws, declared their willingness to yield to the British parliament the power to make such regulations of external trade as were *bona fide* meant to benefit trade, and not to raise a revenue from Americans without their own consent. This solution could have been only temporary at best, and war cut off any discussion of it.

42. The work of quiet revolution was begun in March 1763, in the closing hours of the Bute ministry, Charles Townshend being first lord of trade and administrator of the colonies. It was decided to make a point of having all the American judges and other officials hold office during the king's pleasure, and to make their salaries independent of the colonial assemblies. The army estimates were increased by an American standing force of twenty regiments, to be paid for by Great Britain for the first year, and thereafter out of a revenue to be raised in America by Act of Parliament. Bute's purposes were political,—the diminution of democracy in America. The

Wilkes uproar drove him out of power before he could develop his plans; but his successor, Grenville, followed them out for financial reasons, and in February 1765 the Stamp Act "was passed through both Houses with less opposition than a turnpike bill."

The Stamp Act.

43. For the past two years the colonists had had other things to think of. Under Grenville the Acts in restraint of colonial trade (§§ 20, 21), which had been allowed to become practically obsolete, were put into force with unsparing rigour. The numbers of the customs officers were increased; their duties were more plainly declared; naval officers were encouraged to take the oaths of customs officers and share in the plunder of the commerce which had grown up between America and the West Indian Islands and other parts of the world. Search was constant; confiscation usually followed search; and appeal was even more costly than confiscation. In the confusion arising from the efforts of American commerce to escape its new enemies, it was not wonderful that other questions were allowed to go by default. But the mutterings of resistance were heard. The Massachusetts assembly protested against any schemes to create a standing army in America, to make officers independent of the assemblies, or to raise a revenue without consent of the assemblies, and appointed a committee to secure the united action of all the colonies. This was the first movement in the struggle for union. Its importance was hidden from the ministry by the official class in the colonies, whose members—the governors, judges, and other crown officials—continued to urge a persistence in the new policy, and to represent the Adamses, Otis, and the other colonial leaders as animated by a perverse desire to destroy the unity of the empire.

44. The revenue to be raised by the Stamp Act was to come from the sale of stamps and stamped paper for marriage licences, commercial transactions, suits at law, transfers of real estate, inheritances, publications, and some minor sources of revenue. With it was another startling provision,—a command to the colonial assemblies to furnish the royal troops in America with fuel, candles, vinegar, bedding, cooking utensils, and potables, and permission to billet the troops in inns, alehouses, barns, and vacant houses. The colonies were thus to be taxed without their consent; the revenue derived therefrom was to be devoted to the support of a standing army; and that army was in turn to be used for the maintenance of the scheme of taxation. Yet no one in England seems to have dreamed of American resistance to it; and Grenville was able to say in 1770 that he "did not foresee the opposition to the measure, and would have staked his life for obedience."

45. The news of the passage of the Stamp Act caused all America to hum with the signs of resistance, but for-Resist-
cible resistance was at first repudiated everywhere. It took the shape, really more significant, of declarations by the colonial assemblies, the lower or popular houses of the legislatures. The Virginia assembly, under the lead of Patrick Henry and the younger members, took the first step (May 1765), by a declaration of colonial rights covering the right of each colony to make its own laws and impose and expend its own taxation. The Massachusetts assembly followed with the formal proposal of an American Congress, to be composed of representatives of all the colonies. South Carolina seconded the call; and the first step on the road to union was taken.

ance to
the Stamp
Act.

46. Outside of these formal steps there were signs of a less formal popular resistance. Even peaceable resistance was *pro tanto* a suspension of royal and parliamentary authority in the colonies; and it was probably inevitable that the colonial assemblies should succeed to the power

"Sons of Liberty."

during the interregnum before the organization of a real national power. But a temporary chaos was as inevitable; and the form it took was the formation, particularly in the North, of popular organizations known as "Sons of Liberty," the name being taken from a chance allusion in one of Barré's speeches in the House of Commons. These, backed frequently by the town organizations, forced the stamp officers to resign, and destroyed the stamps wherever they could be found. The Connecticut stamp-officer, as he rode into Hartford on his white horse to deposit his resignation, with a thousand armed farmers riding after him, said that he felt "like death on the pale horse, with all hell following him." Newspapers and pamphlets rang every possible change on Coke's dictum that "an Act of Parliament contrary to Magna Charta was void," and with warnings to stamp-officers that they would be considered enemies to the liberties of America if they attempted to carry out their duties. When the day broke on which the Act was to go into operation (November 1, 1765), America had neither stamps nor stamp-officers with which to fulfil its provisions.

Stamp-Act Congress.

47. The proposed Congress, commonly called the "Stamp-Act Congress," met at New York (October 7, 1765),—New Hampshire, Virginia, North Carolina, and Georgia being acquiescent but not represented. It petitioned the king, the House of Commons, and the House of Lords to recognize fully "the several governments formed in the said colonies, with full powers of legislation, agreeably to the principles of the English constitution." It also put forth a declaration of colonial rights, acknowledging allegiance to the crown, and claiming "all the inherent rights and privileges of natural-born subjects within the kingdom of Great Britain," including the right of petition, of trial by jury, of taxation by representatives, and of granting supplies to the crown, and protesting against the Stamp Act and the various Acts in restraint of trade. The action of this congress was thus purely declaratory; there was no attempt to legislate; and the importance of the meeting was in its demonstration of the possibility of union and of one road to it.

Repeal of the Stamp Act.

48. In the meantime the Grenville ministry had fallen (July 1765), and the Rockingham ministry (March 1766) repealed the Stamp Act. The repeal was supported by Pitt, and Whigs who agreed with him, on the distinction that taxation by parliament without colonial representation was in violation of the essential principles of the British constitution, but that the power of parliament to legislate in every other point for all parts of the empire must be maintained (§ 21). Nevertheless, the repeal was preceded by a declaration of the power "of the king in parliament to bind the colonies and people of America in all cases whatsoever."

49. The colonists received the repeal with an outburst of rejoicing loyalty. They cared little for Pitt's distinction of powers, or even for the declaratory Act: it seemed to them merely the honours of war with which the ministry was to be allowed to retire. It really meant much more. The ruling interest in the home Government, disordered for the moment by its sudden discovery of the strength and union of the colonies, had drawn back, but not for ever. All through the year an undercurrent of irritation against the colonies is evident; and, when (June 1767) Townshend, the chancellor of the exchequer, had wrested the lead from the other members of the Grafton ministry, he passed through both Houses the bill for taxing imports into the colonies, to go into effect on 20th November following. It laid duties on glass, paper, painters' colours, lead, and tea. As the proceeds were for the exchequer, they were to be distributed by the crown; and there was no secret that the design was to provide salaries for the crown

servants in North America. About the same time other Acts established a board of customs at Boston, legalized the "writs of assistance," and suspended the New York assembly until it should obey the Billeting Act. Townshend died soon after, leaving his system as a legacy to his successor, Lord North.

50. The New York assembly granted the necessary money, said nothing as to its use, and escaped further molestation. Beyond this the Acts accomplished nothing. Their advocates had urged that the colonies admitted the power of parliament to control external commerce, and that the new taxes were an exercise of such control. If they desired a purely technical triumph they had it, for their logic was sound, and the taxes remained on the statute-book. But, as the colonies ceased to import the non-taxed articles, by popular agreement and enforcement, the taxes amounted to little. The irritations caused by the enforcement of the Navigation Acts only increased in bitterness; and the official class in the colonies, on whom must for ever rest the responsibility for nine-tenths of the difficulties which followed, lost no chance of representing every pamphlet, newspaper letter, or public meeting as incipient rebellion. A popular outburst in Boston (June 1768), following the seizure of John Hancock's sloop "Liberty," was thus used to give that town an unenviable reputation for disorder and violence. Colonial officials everywhere openly or secretly urged the strongest measures; and all the while the colonists, with the cautious tenacity of their race, were acting so guardedly that the British attorney-general was compelled to say, "Look into the papers and see how well these Americans are versed in the crown law; I doubt whether they have been guilty of an overt act of treason, but I am sure they have come within a hair's-breadth of it."

51. The colonial officials, hoping for salaries independent of the assemblies, began to show a disposition to govern without those bodies. When the Massachusetts assembly refused by a large vote to withdraw its circular letter to the other assemblies urging united petition to the king alone, as an umpire between themselves and the British parliament, for redress of grievances, the assembly was prorogued, and did not reassemble for a year. As a gentle hint of a possible mode of re-establishing popular government, delegates from the towns met in convention at Boston (September 1768), renewed the protests against the Acts of the ministry, and provided for the maintenance of public order. In the following December and January parliament passed a vote of censure on this proceeding, and advised that those who had taken part in it should be sent to England for trial on the charge of treason. This was a new grievance for the assemblies. They passed remonstrances against any attempt to send Americans beyond seas for trial, as a violation of the citizen's right to trial by a jury from the vicinage; and their governors at once prorogued them. Civil government in the colonies, under its original constitution, was evidently in sore straits.

52. In September 1768 two British regiments which the colonial officials had succeeded in obtaining arrived at Boston. Instead of a rebellious population they found their most formidable opponents in minute law points, which were made to beset them at every turn. The Billeting Act required the ordinary barracks to be filled first: the council would assign no quarters in town until the barracks outside were filled. The assembly was not in session to authorize anything further, and the governor did not dare to summon it. The troops, who had marched into the town as into a captured place, with sixteen rounds of ammunition per man, were presently without a place in which to cook their dinners, until their commander hired houses out of the army chest. It was natural that

Non-importation agreement.

Difficulties at Boston.

Townshend's Acts.

he should denounce "this country, where every man studies law." Exasperating and exasperated, the troops lived on in Boston until (March 1770) a street brawl between soldiers and citizens resulted in the death of five of the latter and the injury of six more. Still the town kept its temper. The captain who had given the order to fire was seized by the civil authorities, subjected to the ordinary trial for murder, defended by John Adams and Quincy, two Massachusetts leaders, at the hazard of their own popularity, and acquitted for lack of evidence. But, while according a fair trial to the soldiers, the colonial leaders at last represented so plainly to the crown officials the imminence of an outbreak that the troops were removed from the town to a fort in the harbour.

The colonial governments.

53. The most significant point in the history of the four years 1770-73 is the manner in which the ordinary colonial governments continued to go to pieces. When the assemblies met they would do nothing but denounce the Acts of the ministry; when they were prorogued the colony was left without any government for which there was popular respect. This was about the state of affairs which the crown officials had desired; but, now that it had come, they were not at all prompt in their use of it. Divorced from regular government, the people put out still stronger efforts to enforce the non-importation agreements which had kept down the revenues from the tax laws of 1767. About 1773 a further development appeared. As soon as the assemblies met for their annual sessions, and before the governors could find excuse for proroguing them, they appointed "committees of correspondence," to maintain unity of action with the other colonies. Thus, even after prorogation, there was still in existence for the rest of the year a semi-official representation of the colony. This was nearly the last step on the way to colonial union.

Western settlement.

54. The whites had already crossed the Alleghenies. In 1768 parties from North Carolina entered Tennessee; and in 1769 Boone (p. 788) and a party of Virginians entered Kentucky. The settlement of Tennessee was hastened by difficulties with Tryon, the governor of North Carolina. Tryon was one of the worst of the crown officials; and his government had been a scandal, even for those times. The people, denied justice and defrauded of legislative power, rose in hasty insurrection and were defeated. Tryon used his victory so savagely as to drive an increasing stream of settlers over the mountains into Tennessee. The centres of western settlement, however, were but few. There was one at Pittsburgh, another at Detroit, another near the Illinois-Indiana boundary, another in Kentucky, another near the present city of Nashville, Tennessee; but none of these, except, perhaps, Detroit, was more than a hunting or trading camp. Some efforts had been made to erect crown colonies, or to settle grants to companies, in the western territory, but they came to nothing. The settlements still clung to the coast.

The tea tax.

55. In April 1770, encouraged by some symptoms of a failure of the non-importation agreements, the ministry had taken off all the taxes of 1767, retaining only that upon tea—threepence per pound. The general popular agreement was still strong enough to prevent the importation of this single luxury; and it was found in 1772 that the tax produced but about £80 a year, at an expense of two or three hundred thousand for collection. Besides, the East India Company had been accumulating a stock of teas, in anticipation of an American market, of which the tea-tax had deprived it. In May 1773 the ministry took a fresh step: the tax was to be retained, but the Company was to be allowed a drawback of the entire duty, —so that the colonists, while really paying the tax and yielding the underlying principle, would get their tea cheaper than any other people. The first cargoes of tea

under the new regulations were ordered home again by popular meetings in the American ports, and their captains generally obeyed. At Boston the governor refused to clear the vessels for Europe; and, after prolonged discussion, some fifty persons, disguised as Indians, went on board the vessels and threw the tea into the harbour in the presence of a great crowd of lookers-on (December 16, 1773).

56. It was not possible that the term American should suddenly supplant that of Englishman; but the successive steps by which the change was accomplished are easily perceptible. Using one of the old English political phrases, the supporters of colonial privileges had begun about 1768 to adopt the name of "American Whigs." Its increasing substitution for that of Englishmen was significant. Within a few years the terms "continental," or "the continent," began to take on a new meaning, referring to a union of the colonies at which men hardly ventured to hint clearly. It meant a good deal, then, when men said very truly that "the whole continent" applauded the "Boston tea-party." It was the first spoken word of the new national spirit. Nothing was less understood in England; the outbreak left America in general, and Boston in particular, hardly a friend there. The burning of the revenue schooner "Gaspee" in Narragansett Bay (June 1772) had seemed to the ministry almost an act of overt rebellion; this was rebellion itself.

57. In March and April 1774, on receipt of full intelligence of the proceedings at Boston, the ministry passed a series of Acts which made open struggle only a question of time. The Boston Port Act shut up the town of Boston against all commerce until the destroyed tea was paid for and the town returned to loyalty. The Massachusetts Act changed the charter of that colony: the crown was now to appoint governor, council, and sheriffs; the sheriffs were to select juries; and town meetings, unless by permission of the governor, were forbidden. Gage, the British commander-in-chief in the colonies, was made governor under the Act, and four regiments were given him as a support. Any magistrates, officers, or soldiers indicted under colonial laws were to be sent for trial to Nova Scotia or Great Britain. The billeting of soldiers in the town of Boston was legalized. The Quebec Act extended the boundaries of the province of Canada over the whole territory lying north of the Ohio and east of the Mississippi. Here the ministry rested.

The "Intolerable Acts."

58. The news of these Acts of Parliament crystallized Union. every element of union in the colonies. The attack on the charter of Massachusetts Bay was undoubtedly the most effective. The charters of Connecticut and Rhode Island were the freest of the colonies; but that of Massachusetts was certainly next to them. If Massachusetts was not safe against such an attack, no colony was safe. The ministry had forced an issue on the very point on which the colonial and imperial theories were irreconcilable. The Boston Port Act furnished a grievance so concrete as to obviate the necessity of much argument on other points. The Quebec Act, with its attempt to cut off the northern colonies from the western expansion to which they all looked hopefully, was bad enough in itself, but it brought up with it the element of religious suspicion. For years the distinctively Puritan element had dreaded an attempt to establish the Church of England in the colonies; and the inclination of American Episcopalians to look to the home Government for relief against unjust local restrictions had not helped to decrease the feeling. The Puritan element could see little real difference between Episcopacy and Catholicism; and, when it was found that the Quebec Act practically established the Roman Catholic system in the new territory, the old dread revived to give the agitation a hidden but strong motive.

First
Conti-
nental
Con-
gress.

59. The necessity of another Congress was universally felt. On the suggestion of Virginia and the call of Massachusetts, it met at Philadelphia (September 5, 1774). All the colonies but Georgia were represented; and Georgia was so certainly in sympathy with the meeting that this is commonly known as the First Continental Congress, the first really national body in American history. Its action was still mainly deliberative. It adopted addresses to the king, and to the people of the colonies, of Quebec, and of Great Britain, and passed a declaration of colonial rights, summing up the various Acts of Parliament which were held to be in violation of these rights. But its tone was changed, though its language was still studiously controlled and dignified. It was significant that, for the first time, the two Houses of parliament were ignored in the matter of petitioning: it was at last seen to be an awkward concession even to memorialize parliament. The tone of a sovereign about to take his seat is perceptible in the letter of Congress to the colonies which had not yet sent delegates. And at least two steps were taken which, if not an assumption of sovereign powers, were evidently on the road to it. The first was the preparation of Articles of Association, to be signed by the people everywhere, and to be enforced by committees of safety chosen by the people of cities and towns. These articles bound the signers to stop the importation of all goods from, and the exportation of all goods to, Great Britain and Ireland, the use of such goods, and the slave trade. The manner of the enforcement of the articles was evidently an incipient suspension of all authority proceeding from the mother country and the substitution of a general popular authority for it. The other step was a resolution, adopted October 8, as follows:—"That this Congress approve the opposition of the inhabitants of the Massachusetts Bay to the execution of the late Acts of Parliament; and, if the same shall be attempted to be carried into execution *by force*, in such case all America ought to support them in their opposition." This was simply an ultimatum: in the opinion of Congress, the ministry could take no further step except that of attempting to enforce its Acts, and the colonies would resist such an attempt as an act of war. Before the next Congress met the conditions had been fulfilled. The agents of the ministry had applied force; Massachusetts had resisted by force; and the new Congress found itself the representative of a nation at war, still acknowledging the king, but resisting the operations of his armies. Having summoned a new Congress to meet at Philadelphia on the 10th of May following, and having cleared the way for its action, the First Continental Congress adjourned.

Its ulti-
matum.

60. It is an unpleasant task to record the successive steps by which two peoples, so exactly similar to one another in every characteristic, so far removed from one another, and so ignorant of one another's feelings, advanced alternately to a point where open collision was inevitable. From the standpoint of "no taxation without representation," which Pitt and his school of Whigs had approved, the colonists had now been driven by the suicidal logic of their opponents to the far more consistent position of "no legislation without representation," which the Pitt school had never been willing to grant, and which was radically inconsistent with the British "imperial" theory. Either the previous legislation of parliament was to remain a dead letter, or it must be executed by force; and that meant war. Massachusetts was already on the brink of that event. Gage, the new governor, had refused to meet the assembly; he had fortified himself in Boston, and was sending out spies as if into hostile territory. All regular government was suspended or remanded to the towns; and the people were organized into "minute men,"

pledged to move at a minute's notice. The first hostile movement of Gage would be the signal for the struggle. War, in fact, had come to be a possibility in the thoughts of every one. The new governor of Canada, Carleton, was sent out with instructions to levy the people and Indians of that province, in order that they might be marched against rebels in any province of North America. Governor Tryon's defeat of the insurgent people of North Carolina at the Alamance (§ 54) furnished a tempting precedent to Governor Gage in Massachusetts. There was strong pressure upon him to induce him to follow it. The king's speech at the opening of parliament (November 29, 1774) spoke of the prevalent "resistance and disobedience to the law" in Massachusetts; the ministry urged Gage to arrest the colonial leaders, even though hostilities should follow; the two Houses of Parliament presented a joint address to the king, declaring Massachusetts to be in rebellion, and offering all the resources of the empire to suppress the rebellion; and the king, in reply, announced his intention of acting as parliament wished.

61. The inevitable collision was narrowly escaped in February 1775. Gage sent a water expedition to Salem to search for powder; but the day was Sunday, and a conflict was prevented by the ministers. Another expedition (April 19) was more momentous. It set out for Concord, a little village some 20 miles from Boston, to seize a stock of powder which was reported to be gathered there. At daybreak the troops marched into the village of Lexington, on their road. They found some minute men who had been hastily summoned, for intelligence had been sent out from Boston that the expedition was coming. There was a hurried order from an officer that the militia should disperse, then a volley from his men and a few answering shots, and the first blood of the American revolution had been shed. The troops went on to Concord and destroyed the stores there. But by this time the whole country was up. Messengers were riding in every direction, arousing the minute men; and their mustering made the return to Boston more dangerous than the advance had been. When the troops began their return march the continuous fire from fences, trees, and barns along the route soon converted the retreat into a rout. The opportune arrival of a rescuing party from Boston saved the whole force from surrender, but the pursuit was kept up until the expedition took refuge under the guns of the war-vessels at the water-side. The next morning the isthmus which connected the town of Boston with the mainland was blockaded; the siege of Boston was formed; and the revolution had begun.

62. The news of Lexington and Concord fights set the continent in a flame, but every feature of the outburst showed the still thoroughly English characteristics of the people. For nine long years they had been schooling themselves to patience; and, as their impatience became more difficult to control, it was shown most strongly in their increasingly scrupulous care to insist upon the letter of the law. Even in the first open conflict the colonists were careful to base their case on their legal right to use "the king's highway"; and Congress carefully collected and published depositions going to show that the troops had violated this right and had fired first. There was everything in the affairs of Lexington and Concord to arouse an intense popular excitement: the mustering of undisciplined farmers against regular troops, the stern sense of duty which moved it, the presence and encouragement of the ministers, the sudden desolation of homes which had never known war before, were things which stirred every pulse in the colonies when they were told. But there was no need of waiting for such stories. When the dam burst, the force which had been stored up for nine years took

Lexing-
ton and
Concord.

everything away before it. The news was hurried by express along the roads to the southward; men left the plough in the furrow when they heard it, and rode off to Boston; town committees of safety collected money and provisions and sent them to the same point; and before the end of the month the mainland around Boston harbour was occupied by a shifting mass of undisciplined half-armed soldiers, sufficient to keep the British troops cooped up within the peninsula on which the town was built.

Popular
govern-
ments.

63. The overturning of the royal governments in North America followed rapidly, as the news of the fights at Lexington and Concord spread abroad. In one colony after another the lower houses of the colonial legislatures, taking the name of "provincial congresses," met and assumed the reins of government; the officers of militia and subordinate magistrates accepted commissions from them; and the colonial officials, to whose advice so much of the course of events had been due, fled to England or to the nearest depôt of royal troops. On the day (May 10, 1775) when the stronghold of Ticonderoga, the key of the gateway to Canada, was taken by surprise by an American force under Allen (p. 787), giving the besiegers of Boston a welcome supply of weapons and ammunition, the Second Continental Congress met at Philadelphia. It came, under new circumstances, to redeem the pledge which its predecessor had given that all the colonies would support Massachusetts in resisting force by force. It was thus the representative of a united people, or of nothing. The struggle for union had been so far successful.

Second
Contin-
ental
Congress.

64. This fact of union has coloured the whole subsequent history of the country. The Articles of Association had really preceded it by a substitution of general popular government, however clumsy in form, for the previously recognized governments; in so far the authority of the various colonies was also suspended, and a general national organization took their place. It was soon found that the colonial organizations had too much innate strength to be got rid of in this summary fashion; they held their own, and, as soon as imminent danger had disappeared, they succeeded in tearing so much power from the Continental Congress as to endanger the national existence itself. But, when the Second Continental Congress met, it met (as Von Holst maintains) as a purely revolutionary body, limited by no law, and by nothing else but by its success in war and the support which it was to receive from the people, without regard to colony governments. With the energy and recklessness of a French revolutionary body it might have blotted out the distinctions between colonies, and established a centralized government, to be modified in time by circumstances. In fact, it took no such direction. It began its course by recommendations to the new colonial governments; it relied on them for executive acts; and, as soon as the new colonies were fairly under way, they seized on the power of naming and recalling the delegates to the Congress. From that time the decadence of the Congress was rapid; the national idea became dimmer; and the assertions of complete sovereignty by the political units became more pronounced. This failure of the Second Congress to appropriate the universal national powers which were within its grasp is responsible for two opposite effects. On the one hand, it built up a basis for the future assertion of the notion of State sovereignty, necessarily including the right of secession. On the other, it maintained the peculiar feature of the American Union, its large State liberty, its dislike of centralization, and its feeling that the national power is a valuable but dangerous instrument of development. The effort to find a compromise between the two forces makes up the record of

Failure
of the
first
national
system.

subsequent national politics, ending in the present assertion of the largest possible measure of State rights, but under the guarantee of the national power, not of the State's own sovereignty.

65. The conversion of the former colonies into "States" followed The State hard upon the outbreak of war (§ 72). Since that time the States system. have really been the peculiar feature of the American system. The circumstances just mentioned put them into a position in which they held all real powers of government; and they are still the residuary legatees of all such powers as have not been taken from them by the national power or by their State constitutions. In 1775 they differed very materially in their organization, but there has been a constant tendency to approach a general type, as States have adopted innovations which have proved successful in other States. All have now governors, legislatures of two houses, and State judiciaries. The governor, except in a few States, has a limited veto on legislation, and has a pardoning power. The State legislature is supreme in all subjects relating to the jurisdiction of the State, with two exceptions: the constitution of the United States imposes certain limitations on them (§ 116), and there is an evident tendency in the later State constitutions to prohibit the legislatures from "special legislation," and to provide that, in specified subjects, they shall pass only "general laws," applicable to the whole State and all citizens alike. With these exceptions, it is difficult to imagine a more complete autonomy than is possessed by the States of the American Union. The main restriction upon their action is in its results upon their welfare. They may even repudiate their debts, and there is no power which can make them pay; but, even in respect to this, the results upon the credit of a repudiating State have been enough to check others in any action of the kind. They control the organization of the State into counties, towns, and cities; they touch the life and interests of the citizen in a far larger degree than does the Federal Government; and, in many points, such as that of taxation, their powers are co-ordinate with those of the Federal Government, so that the two departments of the American Governmental system operate on the same subjects. The admission of new States (§ 97) has raised the number of the original thirteen States to thirty-eight (in 1887), and the powers of the new States are exactly those of the old ones.

66. The "force resolution" of the First Congress (§ 59) shows that the national existence of the United States, in a purely political sense, dates from the fulfilment of the conditions of the force resolution—that is, from the first shot fired at Lexington. From that instant the fact of union was consummated in the support given to Massachusetts by the other commonwealths; and George III. was king no longer of thirteen separate kingdoms, but of one. The fact that he did not recognize the union did not alter the fact of union; that was to be decided by events. This success of the struggle for union gave the United States a date for the political, as distinguished from the legal, existence of the nation (April 19, 1775).

IV. THE STRUGGLE FOR INDEPENDENCE: 1775-83.

67. The Second Congress adopted the "army" around Boston as "the American continental army"; rules and articles of war were formulated for it; and Ward, Charles Lee (a British soldier of fortune), Schuyler (p. 790), and Putnam were named as major-generals, with eight brigadiers, and Gates as adjutant-general. Union, though accomplished, was still weak. Sectional interests, feelings, and prejudices were strong; and the efforts of the delegates to accommodate them had, as one result, the appearance of Washington on the historical stage which he was to fill so completely. He had been of special service on the military committee of Congress; and the Massachusetts members—the Adamses and others—saw in him the man whose appointment as commander-in-chief would be most acceptable to all the sections, and would "cement and secure the union of these colonies," as John Adams wrote in a private letter. He was chosen unanimously and commissioned, and set out for Boston. But another collision, the battle of Bunker Hill, had taken place on the date of his commission (June 17).

68. In one of the irregular surgings of the colonial force around Boston, it took possession of Breed's (now known Hill.

as Bunker) Hill, some 75 feet high, commanding Boston, and separated from it by a sheet of water. The British officers might have landed men so as to take the line of entrenchments in the rear, or might have raked it from end to end from the water. They chose to send 2500 men over in boats, and charge straight up the hill. The all-important question was whether the "embattled farmers" within the works would stand fire. Not a shot from the line of entrenchments returned the scattering fire of the advancing column until the latter was within a hundred feet; then a sheet of flame ran along the line, and, when the smoke cleared away, the charging troops were retreating down the hill. The officers moved the men again to the assault, with exactly the same result. At the third assault the ammunition of the farmers was exhausted; but they retreated fighting stubbornly with gun-stocks, and even with stones. "The success," wrote Gage to the ministry, "has cost us dear; the trials we have had show the rebels are not the despicable rabble too many have supposed them to be." He had lost 1100 out of 2500 men. A serious American loss was that of Warren, a Boston leader of high promise.

69. While Washington was endeavouring to form an army out of the heterogeneous material around Boston, another American force was attempting to drive the British out of Canada. On the last day of the year 1775, in an assault on Quebec, one of the leaders, Montgomery (p. 790), was killed, and another, Benedict Arnold, was wounded. Shortly afterwards the American force was driven back into the northern part of New York, near the Canada line, where it held its ground. Congress began in June the issue of bills of credit, or "continental currency," as a substitute for taxation—a most unhappy step. The bills soon began to depreciate. Congress insisted on holding them to be legal tender; but it had not seized, as it might have done, the power of taxation, in order to provide for the redemption of the bills; and its recommendation to committees of safety to treat as enemies of their country those who should refuse to receive the bills at their face value never accomplished its object. Successive emissions of paper enabled Congress to support the army for a few years, and even to begin the organization of a navy. Privateers and public armed vessels had been sent out by the several colonies; the first American fleet, of eight vessels, sailed in February 1776, but its cruise accomplished little.

70. All this time Congress had been protesting its horror of the idea of independence; and the colonial congresses had instructed their delegates not to countenance any such project. The last petition to the king was adopted by Congress in July 1775, and sent to London by the hands of Richard Penn. It besought the king to consider the complaints of the colonists, and to obtain the repeal of the Acts which they had found intolerable. The news of the battle of Bunker Hill had preceded Penn; the king refused to answer the petition; but by a proclamation (August 23, 1775) he announced the existence of open rebellion in the colonies, and called on all good subjects to give any information of those persons in Great Britain who were aiding and abetting the rebellion. This was but the first of a series of attacks on that strong sentiment in Great Britain which felt the cause of the colonies to be the old cause of English liberty. At the opening of the struggle this sentiment was intense: officers resigned their commissions rather than serve in America; the great cities took open ground in favour of the colonies; and some of the English middle classes were mourning for the dead at Lexington. As the war increased in its intensity this sentiment necessarily decreased; but, even while parliament was supporting the war by votes of

more than two to one, the ministry was constantly hampered by the notorious consciousness that the real heart of England was not in it. Even when 25,000 men were voted at the king's wish, provision had to be made to obtain them from Germany. Privilege and officialism were against the colonies; the popular heart and conscience were either ignorant or in favour of them.

71. But in America everything spoke of war. Howe, who had succeeded Gage, passed a very bad winter. His men were often short of supplies; their quarters were uncomfortable; and their efforts to better their position were a severe infliction upon the inhabitants. Along the coast the commanders of British ships acted everywhere as if on the borders of an enemy's country; Gloucester, Bristol, Falmouth, and other defenceless towns were cannonaded; and the flag of the king tended more and more to appear that of an enemy. On the first day of the new year the distinctive standard of the thirteen united colonies was raised at Washington's headquarters. It introduced the stripes of the present flag, but retained the crosses of St George and St Andrew on a blue ground in the corner, the whole implying the surviving acknowledgment of the royal power, with the appearance of a new nation. When independence had eliminated the royal element, the crosses were replaced (1777) by stars, as at present. Congress had been compelled to go so far in national action as to threaten reprisals for the threats of special punishment by the ministry. The first step towards the ultimate application for admission to the family of nations was really taken in November 1775, when Franklin, Jay, and three other delegates were appointed a committee to maintain intercourse with friends of the colonies "in Great Britain, Ireland, and elsewhere"; the main importance of the appointment was in the last two words. The end of the year left independence in the air, though hardly spoken of.

72. Thomas Paine turned the scale (January 9, 1776) Paine. by the publication of his pamphlet *Common Sense*. His argument was that independence was the only consistent line to pursue; that "it must come to that some time or other"; that it would only be more difficult the more it was delayed; and that independence was the surest road to union. Written in simple language, it was read everywhere; and the open movement to independence dates from its publication. In the meantime events were urging Congress on. Washington in March seized and fortified Dorchester Heights, to the south of Boston and commanding it. Before the British could move upon the works, they had been made so strong that the garrison evacuated the place (March 17, 1776), sailing away to Halifax on the fleet. For the moment the British had hardly an organized force within the thirteen colonies; Charles Lee had just seized New York city and harbour; and the ministry seemed not only hostile, but impotent. The spirit of Congress rose with success. It had already ordered (November 25, 1775), on receipt of news of instructions to British war-vessels to attack American seaport towns "as in the case of actual rebellion," that British war-vessels or transports should be open to capture; now (March 23, 1776) it declared all British vessels lawful prize. It then went on (April 6) to open all American ports to the vessels of all other nations than Great Britain, still forbidding the slave trade. It had even opened communication with the French court, which, using the name of a fictitious firm in Paris, was shipping money, arms, and supplies to the colonies. All these were acts of an independent power; and colony after colony, changing the colonial into State forms of government, was instructing its delegates to vote for independence. In May some of the colonies had become too impatient to wait longer, for it was evident that the king had finally ranged himself against the new

Evacuation of Boston.

American nation. Virginia spoke in most emphatic tones ; and one of her delegates, Richard Henry Lee, moved a resolution in Congress for independence, seconded by John Adams (June 7, 1776). A committee to draw up a declaration in conformity with the resolution was chosen, consisting of Thomas Jefferson of Virginia, John Adams, Franklin, Roger Sherman of Connecticut, and Robert R. Livingston of New York ; but the resolution was not adopted until July 2, as follows :—"Resolved that these united colonies are and of right ought to be free and independent States ; that they are absolved from all allegiance to the British crown ; and that all political connexion between them and the state of Great Britain is and ought to be totally dissolved."

Declara-
tion of
Independence.

73. Jefferson had come from Virginia with the reputation of a very ready and able writer ; and the committee, by common consent, left the preparation of the first draft of the Declaration of Independence to him. He wrote it almost at one heat ; and, though parts of it were rejected or modified by Congress, the whole instrument, as it was adopted by that body (July 4, 1776), must stand as Jefferson's own work. John Adams was its champion on the floor of Congress, for Jefferson was not a public speaker, —and the coincidence of the deaths of these two men, just fifty years afterwards (July 4, 1826), was a remarkable one. The language of the Declaration, like that of all the American state-papers of the time, was strong and direct. Ignoring parliament, it took every act of oppression which had been aimed at the colonies as the act and deed of the king ; it concluded that "a prince whose character is thus marked by every act which may define a tyrant is unfit to be the ruler of a free people" ; and it announced the independence of the United States in the terms of the resolution already stated. The date of its adoption is, by the decision of the Supreme Court, the date of the legal existence of the United States in matters of municipal law.

Attack
on the
middle
colonies.

74. Meanwhile clouds were gathering about the young republic. A British expedition was beaten off from Charleston (June 28) ; but two days afterwards a stronger force, under Howe, landed on Staten Island, just below New York city. The ministry, abandoning New England, had decided to transfer the war to the middle colonies. Here was the originally alien element among the colonies (§ 7), though the ministry was disappointed in it ; here was the commercial element, which had sometimes been willing to prefer profit to patriotism ; above all, the Hudson gave a safe path for British frigates, so that the British forces might control at the same time the road into Canada and the moat which should cut off New England from the other colonies. Most of the reasons which made the opening of the Mississippi a severe blow to the Confederacy in 1863 applied to the capture of New York city and the operations in the Hudson river in 1776.

75. Washington had hurried to New York city as soon as Boston had surrendered, but his preparations were not far advanced when Howe appeared (June 30). He and his brother, Admiral Lord Howe, the commander of the fleet, had high hopes of receiving the confidence of both parties to the struggle, by reason of their hereditary connexion with the crown and the liking of the colonies for their elder brother, killed at Ticonderoga ; and they brought conciliatory proposals and the consent of the ministry to an unofficial exchange of prisoners. The country was now committed to independence, and in August Howe began offensive operations. Washington's force numbered 27,000, about four-fifths of them having never seen action ; and about one-third of his army had been placed on Long Island. Howe had 31,000 trained soldiers, largely Hessians ; and he debarked 20,000 of them on Long Island, beating Putnam (p. 790), the American

commander there, and driving him into Brooklyn (August Battle 27). The British hesitated to attack the American works of there, so that Washington was able to draw off the defeated force, and the British followed slowly to the New York side of the river. Through September and October Washington retreated northwards, fighting stubbornly, until he reached the strong defensive positions where the mountains begin to make a figure in the landscape north of New York city. Here he faced about, and prepared to give battle from behind fortifications. Again Howe hesitated, and then turned back to occupy New York.

76. Howe was cut off from the water-way to Canada by Washington's fortification of the highlands, but his lieutenant, Cornwallis, secured a lodgment by surprise on the other side of the Hudson, and thus drew Washington across the river to oppose him. Forced to retreat through New Jersey, pursued by the British, Washington at least used up the month of December in the retreat. But affairs were in a desperate plight. His army had been driven across the Delaware ; the British held all New Jersey, and were only waiting for the river to freeze over to "catch Washington and end the war" ; Philadelphia was in a panic, and Congress had taken refuge in Baltimore, leaving Washington with almost dictatorial powers ; hosts of half-hearted people were taking British protections and returning to their allegiance ; and the time was one which "tried men's souls." Washington's soul was proof against all tests ; and in the midst of his discouragements he had already planned that which was to be the turning-point of the war. The advanced post of the British was one of Hessians, under Rahl, at Trenton, on the Delaware. Seizing all the boats on the river, and choosing the night of Christmas, on the probability that the Hessians would be drunk, he crossed the river, assaulted the town with the bayonet, and captured the garrison. Taking his prisoners to Philadelphia, he recrossed the river on the last day of the year, and reoccupied Trenton. Cornwallis brought almost all his available forces towards that place ; and Washington's diminishing army was in greater danger than before. Leaving his camp-fires burning, he abandoned his position by night, swept around the sleeping British forces, met, fought, and captured at Princeton (January 3, 1777) a detachment on its march to Trenton, and threatened the British base of supplies at New Brunswick. It was only a threat ; but it served its purpose of drawing Cornwallis off from Philadelphia.

Washington's
retreat.

Battles of
Trenton

and
Princeton.

77. New Jersey is crossed from south-west to north-east by a spur of the Alleghanies. Thus far operations had been confined to the flat country to the south ; Washington now swept on to the northern or mountainous part, and the day after Princeton fixed his headquarters at Morristown, where they really remained almost all through the rest of the war. He was aided by the unwillingness of the British to attack entrenchments. His long line across New Jersey was everywhere strong ; the British could now reach Philadelphia only by passing in front of his line and risking a flank attack ; and they at once drew in their outposts to New Brunswick. With the exception of the occupation of Newport by the British, and attacks on minor outlying places, as Danbury, there was a short breathing space.

78. Kalb, Kosciusko, Conway, and other foreign officers were already serving in the American army ; Pulaski (p. 790), Steuben (p. 790), and others were soon to come. Some of the minor foreign acquisitions of this sort were selfish, conceited, and troublesome ; the most unselfish and devoted was the young Marquis de la Fayette, who came this year with a shipload of supplies as his gift to the republic. Franklin made his appearance at the French court (December 7, 1776) as one of the American envoys, and

Franklin.

soon took the lead in negotiations. Shrewd, sensible, farsighted, and prompt, never missing or misusing an opportunity, he soon succeeded in committing the French Government, in all but the name, as an ally of the United States; and, though his success with other European courts was small, he opened the way for the general commercial treaties which followed the war. His unofficial influence was a more important factor in his work. Carefully maintaining the character of a plain American burgher, he seemed to the French the veritable man of nature for whom they had been longing. The pithy sense and homely wit which had given force to his *Poor Richard's Almanac* had impressed even his unemotional countrymen strongly; his new audience took them as almost inspired. He, and his country with him, became the fashion; and it became easier for the Government to cover its own supplies to the insurgents by an appearance of embarrassment in dealing with the enthusiasm of its subjects. The foreign aid, however, did the Americans a real harm. Congress, relying upon it, grew more and more into the character of a mere agent of the States for issuing paper and borrowing money; and the taxing function, which should have been forced upon it from the beginning, fell more positively into the hands of the States. As the national character of Congress dwindled, the State jealousies and ambitions of its delegates increased; little cliques had their favourite officers,—Gates, Charles Lee, Conway, or some other soldier of fortune; and Washington, neglected and harassed by turns, must have found it difficult to face Howe with half his number of men, foil the various competitors for his own position, and maintain his invariably respectful tone towards Congress.

79. In July 1777 Burgoyne, with an army of British, Germans, and Indians, attempted the Hudson river route from the north, and forced his way nearly to Albany. The utter defeat of a detachment at Bennington (August 16) by the farmers of Vermont and New Hampshire under Stark, the atrocities of the Indians before they deserted Burgoyne's standard, and the end of the harvest brought abundant reinforcements to Gates, whom Congress had put in command. He gained the battle of Bemis Heights (Oct. 7), and ten days afterwards forced Burgoyne to surrender near Saratoga. The news of this success brought to Franklin (Feb. 6, 1778) the desire of his heart in a treaty of alliance, offensive and defensive, between the United States and France, and this was followed in the next month by war between Great Britain and France and an ineffectual proposal for reconciliation from Great Britain to the United States, covering colonial representation in parliament and everything short of independence.

80. Meantime Howe had taken the water-route to Philadelphia, by way of the ocean and Chesapeake Bay, and had captured the city (September 25, 1777); but Washington had at least made his army capable of fighting two battles, those of Chad's Ford on the Brandywine (September 11) and Germantown in the outskirts of Philadelphia (October 4), both stubbornly contested. Taking up winter-quarters at Valley Forge, about 20 miles from Philadelphia, he watched Howe vigilantly, and struggled manfully with the responsibilities of supreme command, which the fugitive Congress had again left to him, with the misery and almost despair of his own men, and with the final intrigues of those who now wished to supersede him by the appointment of Gates. In June 1778 the news of the treaty with France, and of the departure of a French fleet and army for America, compelled Clinton, who had succeeded Howe, to set out for New York, in order to reunite his two main armies. Washington broke camp at once, followed him across New Jersey, and overtook the rear at Monmouth, or Freehold (June 29). An indecisive battle enabled the

British to gain New York city; Washington formed his line from Morristown around the north of the city, so as to be of Monmouth. able to interpose between Clinton and Philadelphia or New England; and these positions were maintained until the Yorktown campaign began in 1781. Beyond skirmishes, there were no more important events in the North, except some unsuccessful attempts to recover Newport with French assistance, the capture of Stony Point by Wayne (July 15, 1779), and the treason of the American commander of West Point, Benedict Arnold (p. 787), with the execution of the British adjutant-general, Major John André, whom the Americans had captured within their lines while he was carrying on the negotiations (September 1780).

81. Midsummer 1778 marks the beginning of the end. 33,000 men, the high-water mark of the British army in the United States, had maintained a footing at but two places, New York city and Newport; the ministry, in a war which had no real popular momentum, found German mercenaries an expensive resource; and the Germans were very apt to desert in America. An extraordinary number of leading men in England, while they would not hamper the nation in its struggle, made no scruple of expressing their practical neutrality or their high regard for various American leaders. France was now in the war, and Spain and Holland were soon to be the allies of France. The difficulties of supplying the British army were now aggravated by the presence of French fleets in American waters. English commerce had been decimated by American privateers; and Franklin was gathering vessels in France, in one of which (the "Richard") Paul Jones was to fight with the "Serapis" one of the most desperate naval battles on record (September 23, 1779). Perhaps hopeless of success in the northern and middle States, the ministry decided to begin operations in the south, where it was believed that the slave population would be a fatal source of weakness to the Americans.

82. Late in 1778 a British expedition from New York captured Savannah, and rapidly took possession of the thinly populated State of Georgia. An attempt to retake Savannah in the following year cost the Americans the life of Pulaski. Evacuating Newport, and leaving only troops enough to hold New York city, Clinton sailed southward and captured Charleston (May 12, 1780). Thence his forces swept over South Carolina until they had reduced it to a submission broken by continual outbreaks of partisan warfare under Sumter (p. 790), Marion, and other leaders. This work finished, Clinton returned to New York, leaving Cornwallis in command in the south. As soon as the summer heats had passed away Gates entered the State from the north with a militia army, and was badly beaten at Camden (August 16) by an inferior British force. Even North Carolina now needed defence, and the work was assigned to Greene, one of the best of the American officers developed by the war. The commander of his light troops, Morgan, met his British rival, Tarleton, at the Cowpens (January 17), and inflicted upon the latter the first defeat he had met in the south. This event brought Cornwallis up to the pursuit of the victor. Morgan and Greene retreated all the way across North Carolina, followed by Cornwallis, and then, having raised fresh troops in Virginia, they turned and gave battle at Guilford Court House (March 15, 1781). Greene was beaten, as was usually the case with him, but he inflicted so heavy a loss in return that Cornwallis retired to the coast at Wilmington to repair damages. Greene, energetic as well as cautious, passed on to the south, and gave battle to Rawdon, whom Cornwallis had left in command in South Carolina, at Hobkirk's Hill (April 25), and was beaten again. But Rawdon's loss was so severe that he drew in his lines toward Charleston.

Eutaw Springs. Greene followed, and at Eutaw Springs (September 8) fought the last pitched battle in the South. He was beaten again, but Rawdon again fell back, and thereafter did all that man could do in holding the two cities of Charleston and Savannah. Greene had won no battle, but he had saved the South.

Cornwallis in Virginia. 83. Arnold, now a general in the British service (§ 80), had been sent, early in the year, to make a lodgment in Virginia. It seems to have been believed by the British authorities that the three southernmost States were then secure, and that Virginia could be carved out next. La Fayette was sent to oppose Arnold, but the latter was soon relieved, and in June Cornwallis himself entered the State. He had not been willing to serve with Arnold. Directed to select a suitable position for a permanent post on the Chesapeake, he had chosen Yorktown, where, with the troops already in Virginia, he fortified his army. The general ground was that of M'Clellan's campaign of 1862 (§ 285) and Grant's of 1864-65 (§ 296).

Yorktown. 84. Washington, reinforced by a lately arrived force of 6000 excellent French troops (July 1780) under Rochambeau, was still watching Clinton at New York. The news that De Grasse's French fleet, on its way to the American coast, would enter the Chesapeake, where Cornwallis had left himself open to the chances of such an event, led Washington to conceive the campaign which captured Cornwallis and ended the war. He began elaborate preparations for an attack on New York, so that Clinton actually called upon Cornwallis for aid. Moving down the Hudson, he kept Clinton in ignorance of any movement to the south as long as possible, and then changed the line of march to one through New Jersey. The allied armies passed through Philadelphia, were hurried down the Chesapeake, and drove Cornwallis within his entrenchments at Yorktown. De Grasse had arrived August 30, had defeated the British fleet, and was master of the Chesapeake waters. After three weeks' siege Cornwallis, having exhausted a soldier's resources, surrendered his army of 8000 men (October 19, 1781).

Treaty of peace. 85. The country at large had really been at peace for a long time. Everywhere, except in the immediate neighbourhood of the British forces, the people were working almost with forgetfulness that they had ever been English colonists; and, where the enemy had to be reckoned with, they were looked upon much as the early settlers looked on bears or Indians, as an unpleasant but inevitable item in the debit side of their accounts. Their legislatures were making their laws; their governors, or "presidents," were the representatives whom their States acknowledged; nothing but an American court had the power to touch a particle of the judicial interests of the American people; the American flag was recognized on the ocean; independence was a fact, and the ministry received from the English people so emphatic a call to acknowledge it that it yielded so far as to propose a defensive war. The House of Commons (March 4, 1782) voted to regard as enemies to the king and country all who should advise the further prosecution of the war; the Rockingham ministry succeeded to power, to be followed shortly by the Shelburne ministry; and Rodney's victory over De Grasse gave the new ministries very much the same cover for an unsuccessful peace as Jackson's victory at New Orleans afforded the United States in 1815 (§ 181). Franklin, John Adams, and Jay, the American negotiators, concluded the preliminary treaty of peace, by which Great Britain acknowledged the independence of the United States (Nov. 30, 1782); hostilities ceased; and the definitive treaty of peace was concluded (Sept. 3, 1783). A number of American loyalists (usually called Tories) accompanied the departing armies.

86. In the winter of 1778-79 George Rogers Clark, a Kentucky leader, acting under the authority of the State of Virginia, had led a force of backwoodsmen into the country north of the Ohio river, captured the British posts in it, and made the soil American up to the latitude of Detroit. The treaty of peace acknowledged the conquest, and even more than this. It settled the northern boundary of the United States, so far as the longitude of the Mississippi river, nearly as it now runs; the Mississippi as the western boundary down to 31° N. lat., thence east on that line to the present northern boundary of Florida, and east on that to the Atlantic. Great Britain restored the Floridas to Spain, so that the new nation had Great Britain as a neighbour on the north, and Spain on the south and west. Some disposition had been shown to exclude the Americans from the fishing ground off Newfoundland, but it was abandoned. The United States by the treaty entered the family of nations with recognized boundaries, and all the territory within these boundaries could be recognized by other nations only as the property of the United States. But, so far as internal arrangements were concerned, a great question remained to be settled. There were thirteen organized States, covering but a part of this territory; a part of them claimed to be sole proprietors of the western territory outside of the present State limits; and it remained to be seen whether they would make good their claim, or the other States would compel them to divide, or the new national power would compel as clear an internal as an international recognition of its claim (§ 89).

87. The American army was now disbanded, its officers receiving a grudging recognition of their claims and the privates hardly anything. Poverty was to blame for much of this, and the popular suspicion of military power for the rest. Washington's influence was strong enough to keep the dissatisfied army from any open revolt, though that step was seriously proposed. The organization of the hereditary order of the Cincinnati by the officers brought about a more emphatic expression of public dislike, and the hereditary feature was abandoned. But, wherever the officers and men went, they carried a personal disgust with the existing frame of government which could not but produce its effect in time. Their miseries had been largely due to it. The politicians who controlled the State legislatures had managed to seize the reins of government and reduce Congress, the only body with pretensions to a national character, to the position of a purely advisory body. The soldiery knew instinctively that the lack of power to feed them and clothe them, the payment of their scanty wages in paper worth two per cent. of its face value, were due to the impotence of Congress and the too great power of the States, that the nation presented the "awful spectacle," as Hamilton called it, of "a nation without a national government"; and the commonest toast in the army was "Here's a hoop to the barrel,"—a stronger national government to bind the States together.

The struggle for the establishment of this national government is the next step in the development of the United States, but to reach it naturally it will be necessary to go back into the midst of the struggle for independence.

V. THE STRUGGLE FOR NATIONAL GOVERNMENT: 1777-89.

88. The fact that the Continental Congress was really a revolutionary body, not limited in its powers by any fundamental law imposed by the underlying popular sovereignty, but answering most closely to the British parliament, has already been noted (§ 64). This state of affairs was repugnant to all the instincts and prejudices

Articles
of Con-
federation.

of the American people, and of the delegates who represented them. Just at the time of the Declaration of Independence Congress set about preparing a "form of confederation," which should express exactly the relative powers of the State and national Governments. Its work was finished November 15, 1777, and recommended to the States for adoption. Unluckily, before the work had been finished, the State legislatures had succeeded in establishing their power to appoint and recall at pleasure the delegates to Congress, so that Congress had come to be the mere creature of the State legislatures. The "Articles of Confederation," adopted in 1777, were thus calculated for the meridian of the State legislatures which were to pass upon them. The new government was to be merely "a firm league of friendship" between sovereign States, which were to retain every power not "expressly" delegated to Congress; there was to be but one house of Congress, in which each State was to have an equal vote, with no national executive or judiciary; and Congress, while keeping the power to borrow money, was to have no power to levy taxes, or to provide in any way for payment of the money borrowed—only to make recommendations to the States or requisitions on the States, which they pledged their public faith to obey. The States were forbidden to make treaties, war, or peace, to grant titles of nobility, to keep vessels of war or soldiers, or to lay imposts which should conflict with treaties already proposed to France or Spain. Important measures required the votes of nine of the thirteen States, and amendments the votes of all. Congress had hardly more than an advisory power at the best. It had no power to prevent or punish offences against its own laws, or even to perform effectively the duties enjoined upon it by the Articles of Confederation. It alone could declare war, but it had no power to compel the enlistment, arming, or support of an army. It alone could fix the needed amount of revenue, but the taxes could only be collected by the States at their own pleasure. It alone could decide disputes between the States, but it had no power to compel either disputant to respect or obey its decisions. It alone could make treaties with foreign nations, but it had no power to prevent individual States from violating them. Even commerce, foreign and domestic, was to be regulated entirely by the States, and it was not long before State selfishness began to show itself in the regulation of duties on imports. In everything the States were to be sovereign, and their creature, the Federal Government, was to have only strength enough to bind the States into nominal unity, and only life enough to assure it of its own practical impotence.

The
western
territory.

89. Most of the States signed the Articles at once; New Jersey, Delaware, and Maryland held out against ratifying them for from two to four years. The secret of their resistance was in the claims to the western territory already mentioned (§§ 34, 86). The three recalcitrant States had always had fixed western boundaries, and had no legal claim to a share in the western territory; the Articles, while providing for the decision of disputes between individual States, were careful to provide also that "no State shall be deprived of territory for the benefit of the United States"; and this meant that those States whose charters carried them to the Pacific Ocean, while admitting the national authority to limit their claims by the Mississippi river, were to divide up the western territory among them. New Jersey and Delaware gave up the struggle in 1778 and 1779; but Maryland would not and did not yield until her claims were satisfied.

Its rela-
tions to
the
Union.

90. Dr H. B. Adams has shown that the whole question of real nationality for the United States was bound up in this western territory; that even a "league government" could not continue long to govern a great and growing

territory like this without developing into a real national government, even without a change of strict law; and that the Maryland leaders were working under a complete consciousness of these facts. It is creditable, however, to the change which the struggle for union had wrought in the people that it was not until very late in this struggle that Virginia, the most omnivorous western claimant, proposed to have the Articles go into effect without Maryland, and still more creditable that her proposal hardly received notice from the other States. They were already conscious that the thirteen were really one.

91. The solution of the difficulty was found in 1780. New York's claim. The western boundary of the State of New York had always been very much in the air. Her main claim to her present extensive territory lay in the assertions that the western part had once belonged to the Six Nations of Indians, and that the Dutch, conquering the Six Nations, the English, conquering the Dutch, and New York, conquering the English, had succeeded to these rights. But the Six Nations had exercised an undefined suzerainty over all the Indian tribes from Tennessee to Michilimackinac, covering all the territory in dispute. New York proposed, if Congress would confirm her present western boundary, to transfer to Congress her western claims by conquest, superior to any mere charter claims; and Congress approved the offer as "expressly calculated to accelerate the federal alliance." On March 1, 1781, the New York delegates formally completed the deed of transfer to the United States; on the same day the Maryland delegates signed the Articles; and by this action of the last State the Articles of Confederation came into force as the first attempt to frame a national government.

92. The long struggle had given time for careful consideration of the Articles. Maryland's persistent criticism had prepared men to find defects in them. Conventions of New England States, pamphlets, and private correspondence had found flaws in the new plan of government; but a public trial of it was a necessary preliminary to getting rid of it. The efforts of the individual States to maintain the war, the disposition of each State to magnify its own share in the result, the popular jealousy of a superior power, transferred now from parliament to the central Government, and inflamed by the politicians who saw their quickest road to dignity in the State governments, were enough to ensure the Articles some lease of life. A real national government had to be extorted through the "grinding necessities of a reluctant people."

93. Congress and its committees had already begun to declare that it was impossible to carry on a government efficiently under the Articles. Its expostulations were to be continued for several years before they were heard. In the meantime it did not neglect the great subject which concerned the essence of nationality—the western territory. Virginia had made a first offer to cede her claims, but it was not accepted. A committee of Congress now made a report (1782) maintaining the validity of the rights which New York had transferred to Congress; and in the next year Virginia made an acceptable offer. Her deed was accepted (March 1, 1784); the other claimant States followed; and Congress, which was not authorized by the Articles to hold or govern territory, became the sovereign of a tract of some 430,000 square miles, nearly equal to the areas of France, Spain, and Portugal combined, covering all the country between the Atlantic tier of States and the Mississippi river, from the British possessions nearly to the Gulf of Mexico.

94. In this territory Congress had now on its hands the same question of colonial government in which the British parliament had so signally failed. The manner in which Congress dealt with it has made the United States the

torial
govern-
ment.

The Ordinance of 1787.

country that it is. The leading feature of its plan was the erection, as rapidly as possible, of States, similar in powers to the original States. The power of Congress over the territories was to be theoretically absolute, but it was to be exerted in encouraging the development of thorough self-government, and in granting it as fast as the settlers should become capable of exercising it. Copied in succeeding Acts for the organization of Territories, and still controlling the spirit of such Acts, the Ordinance of 1787 (July 13, 1787) is the foundation of almost everything which makes the modern American system peculiar.

95. The preliminary plan of Congress was reported by a committee (April 23, 1784) of which Jefferson was chairman. It provided for the erection of seventeen States, north and south of the Ohio, with some odd names, such as Sylvania, Assenisipia, Metropotamia, Polypotamia, and Pelisipia. These States were for ever to be a part of the United States, and to have republican governments, and the Ordinance creating them was to be a compact between the Federal Government and each State, unalterable unless by mutual consent. "After the year 1800 there shall be neither slavery nor involuntary servitude in any of the said States, other than in the punishment of crimes whereof the party shall have been duly convicted." This provision, which represented Jefferson's feeling on the subject, was lost for want of seven States in its favour.

96. The final plan of 1787 was reported by a committee of which Nathan Dane, of Massachusetts, was chairman. The prohibition of slavery was made perpetual, and a fugitive slave clause was added (§ 124). The Ordinance covered only the territory north of the Ohio, and provided for not less than three nor more than five States. Ohio, Indiana, Illinois, Michigan, and Wisconsin have been the resultant States. The inhabitants were to be secured in the equal division of real and personal property of intestates to the next of kin in equal degree. At first Congress was to appoint the governor, secretary, judges, and militia generals, and the governor and judges were to make laws subject to the veto of Congress. When the population reached 5000 the inhabitants were to have an assembly of their own, to consist of the governor, a legislative council of five, selected by Congress from ten nominations by the lower house, and a lower house of representatives of one delegate for every 500 inhabitants. This assembly was to choose a delegate to sit, but not to vote, in Congress, and was to make laws not repugnant to "the articles of fundamental compact," which were as follows:—the new States or Territories were to maintain freedom of worship, the benefits of the writ of *habeas corpus*, trial by jury, proportionate representation, bail, moderate fines and punishments, and the preservation of liberty, property, and private contracts; they were to encourage public education and keep faith with the Indians; they were to remain for ever a part of the United States; and they were not to interfere with the disposal of the soil by the United States, or to tax the lands of the United States, or to tax any citizen of the United States for the use of the Mississippi or St Lawrence rivers. These articles were to be unalterable unless by mutual consent of a State and the United States. The transformation of the Territory, with its quite limited government, into a State, with all the powers of an original State, was promised by Congress as soon as the population should reach 60,000.

97. The constitution, which was adopted almost immediately afterwards, provided merely that "Congress shall have power to dispose of, and make all needful rules and regulations respecting, the territory or other property belonging to the United States," and that "new States may be admitted by the Congress into the Union." Opinions have varied as to the force of the Ordinance of 1787. The Southern school of writers have naturally been inclined to consider it *ultra vires* and void; and they adduce the fact that the new Congress under the constitution thought it necessary to re-enact the Ordinance. The opposite school have inclined to hold the Ordinance as still in force. Even as to the territorial provision of the constitution, opinions have varied. The Dred Scott decision held that it applied only to the territory then in possession of the United States, and that territory subsequently acquired, by conquest or purchase, was not to be governed by Congress with absolute power, but subject to constitutional limitations.

98. In the interval of the settlement of the territorial question, the affairs of the "league of friendship" known as the United States had been going from bad to worse, culminating in 1786. The public debt amounted in 1783 to about \$42,000,000, of which \$8,000,000 was owed abroad—in Holland, France, and Spain. Congress had no power to levy taxes for the payment of interest or principal; it could only make requisitions on the States.

In the four years ending in 1786 requisitions had been made for \$10,000,000, and the receipts from them had amounted to but one-fourth of what had been called for. Even the interest on the debt was falling into arrears, and the first instalment of the principal fell due in 1787. To pay this, and subsequent annual instalments of \$1,000,000, was quite impossible. Robert Morris, the financier of the revolution, resigned in 1783, "rather than be the minister of injustice," hoping thus to force upon the States the necessity of granting taxing powers to Congress. Washington, on retiring from the command-in-chief, wrote a circular letter to the governors of all the States, urging the necessity of granting to Congress some power to provide a national revenue. Congress (April 18, 1783) appealed to the States for power to levy specific duties on certain enumerated articles, and 5 per cent. on others. It was believed that with these duties and the requisitions, which were now to be met by internal taxation, \$2,500,000 per annum could be raised. Some of the States ratified the proposal; others ratified it with modifications; others rejected it, or changed their votes; and it never received the necessary ratification of all the States. The obedience to the requisitions grew more lax. Some of the States paid them; others pleaded poverty, and allowed more or less of them to run into arrears; others offered to pay in their own depreciated paper currency; and others indignantly refused to pay in any currency until the delinquent States should pay all their obligations. In 1786 a committee of Congress reported that any further reliance on requisitions would be "dishonourable to the understandings of those who entertain such confidence."

99. In the States the case was even worse. Some of the States had been seduced into issuing paper currency in such profusion that they were almost bankrupt. Great Britain, in the treaty of peace, had recognized the independence of the individual States, naming them in order; and her Government followed the same system in all its intercourse with its late colonies. Its restrictive system was maintained, and the States, vying with each other for commerce, could adopt no system of counteracting measures. Every possible burden was thus shifted to American commerce; and Congress could do nothing, for, though it asked for the power to regulate commerce for fifteen years, the States refused it. The decisions of the various State courts began to conflict, and there was no power to reconcile them or to prevent the consequences of the divergence. Several States, towards the end of this period, began to prepare or adopt systems of protection of domestic productions or manufactures, aimed at preventing competition by neighbouring States. The Tennessee settlers were in insurrection against the authority of North Carolina; and the Kentucky settlers were apparently disposed to cut loose from Virginia, if not from the United States. Poverty, with the rigid execution of process for debt, drove the farmers of western Massachusetts into an insurrection which the State had much difficulty in suppressing; and Congress was so incompetent to aid Massachusetts that it was driven to the expedient of imagining an Indian war in that direction, in order to transfer troops thither. Congress itself was in danger of disappearance from the scene. The necessity for the votes of nine of the thirteen States for the passage of important measures made the absence of a State's delegation quite as effective as a negative vote. In order to save the expense of a delegation, the States began to neglect the election of them, unless they had some object to obtain by their attendance. It was necessary for Congress to make repeated and urgent appeals in order to obtain a quorum for the ratification of the treaty of peace with Great Britain. In 1784 Congress even broke up in

Difficulties of the confederation;

States;

of Congress.

disgust, and the French minister reported to his Government—"There is now in America no general government, —neither Congress, nor president, nor head of any one administrative department." Everywhere there were symptoms of a dissolution of the Union.

100. Congress was evidently incompetent to frame a new plan of national government; its members were too dependent on their States, and would be recalled if they took part in framing anything stronger than the Articles. The idea of a convention of the States, independent of Congress, was in the minds and mouths of many; Thomas Paine had suggested it as long ago as his *Common Sense* pamphlet: "Let a continental conference be held, to frame a continental charter, drawing the line of business and jurisdiction between members of Congress and members of assembly." To a people as fond of law and the forms of law as the Americans there was a difficulty in the way. The Articles had provided that no change should be made in them but by the assent of every State legislature. If the work of such a convention was to be subject to this rule, its success would be no greater than that of Congress; if its plan was to be put into force on the ratification of less than the whole number of States, the step would be more or less revolutionary. In the end the latter course was taken, though not until every other expedient had failed; but the act of taking it showed the underlying consciousness that union, independence, and nationality were now inextricably complicated, and that the thirteen had become one in some senses.

101. The country drifted into a convention by a roundabout way. The navigation of Chesapeake Bay needed regulation; and the States of Maryland and Virginia, having plenary power in the matter, appointed delegates to arrange such rules. The delegates met (1785) at Washington's house, Mount Vernon; and Maryland, in adopting their report, proposed a meeting of commissioners from all the States to frame commercial regulations for the whole. Virginia acceded at once, and named Annapolis, in Maryland, as the place. The convention met (1786), but only five States were represented, and their delegates adjourned, after recommending another convention at Philadelphia in May 1787.

102. Congress had failed in its last resort—a proposal that the States should grant it the impost power alone; New York's veto had put an end to this last hope. Confessing its helplessness, Congress approved the call for a second convention; twelve of the States (all but Rhode Island) chose delegates; and the convention met at Philadelphia (May 14, 1787), with an abler body of men than had been seen in Congress since the first two Continental Congresses. Among others, Virginia sent Washington, Madison, Edmund Randolph, George Mason (p. 789), and George Wythe; Pennsylvania Franklin, Robert and Gouverneur Morris, and James Wilson; Massachusetts Rufus King, Gerry, and Strong; Connecticut William S. Johnson, Sherman, and Ellsworth; New York Hamilton; New Jersey Paterson; and South Carolina the two Pinckneys (p. 790) and Rutledge.¹ With hardly an exception

the fifty-five delegates were clear-headed, moderate men, with positive views of their own, and firm purpose, but with a willingness to compromise.

103. Washington was chosen to preside, and the convention began the formation of a new constitution, instead of proposing changes in the old one. Two parties were formed at once. The Virginia delegates offered a plan, The Virginia plan, proposing a Congress of two houses, having power to legislate on national subjects, and to compel the States to fulfil their obligations. This is often spoken of as a "national plan," but very improperly. It was a "large State" plan, proposed by those States which had or hoped for a large population. It meant to base representation in both houses on population, so that the large States could control both of them, and it left the appointment of the president or other executive and the Federal judges to Congress,—so that the whole administration of the new government would fall under large-State control. On behalf of the "small States" Paterson of New Jersey brought in another plan. It continued the old Confederation, with its single house and equal State vote, but added the power to regulate commerce and raise a revenue, and to compel the States to obey requisitions. The State representation was fortunate. New Hampshire's delegates did not attend until after those of New York (then classed as a small State) had retired from the convention in anger at its evident drift towards the "large-State" plan. The large States had a general majority of six to five, but the constant dropping off of one or more votes, on minor features, from their side to that of the small States prevented the hasty adoption of any radical measures. Nevertheless, the final collision could not be evaded; the basis of the two plans was in the question of one or two houses, of equal or proportionate State votes, of large-State supremacy or of State equality. In July the large States began to show a disposition to force their plan through, and the small States began to threaten a concerted withdrawal from the convention.

104. The Connecticut delegates, from their first appearance in the convention, had favoured a compromise. They had been trained under the New England system, in which the assemblies were made up of two houses, one repre-

N.Y., April 29, 1827. He graduated at Harvard College in 1777, and served as a Massachusetts member of the Continental Congress from 1784 to 1786. Removing to New York, he was elected United States senator from that State, serving in 1789–96, and was minister to Great Britain from 1796 to 1803. From 1804 to 1812 he was the Federalist candidate for the vice-presidency.—EDMUND RANDOLPH was born in Virginia, Aug. 10, 1753, and died in Frederick county, Va., Sept. 12, 1813. He became a lawyer, and, though the son of a leading royalist, entered the American revolutionary army as Washington's aide-de-camp. He served as governor of his State, and as attorney-general and secretary of state under Washington, resigning in 1795 because of the discovery that he was in correspondence with the French minister.—JOHN RUTLEDGE was born at Charleston, S.C., in 1739, and died July 23, 1800. He studied law at the Temple (London), served in the Continental Congress, 1774, was governor of his State from 1779 to 1782, and afterwards was chief justice.—ROGER SHERMAN was born at Newton, Mass., April 19, 1721, and died at New Haven, Conn., July 23, 1793. He was a shoemaker, who, removing to New Milford, Conn., studied law, and served as judge of a State court from 1765 to 1789, as member of the house of representatives from 1789 to 1791, and as United States senator from 1791 to 1793.—JAMES WILSON was born near St Andrews, Scotland, about 1742, and died at Edenton, N.C., Aug. 28, 1798. Emigrating to the United States in 1766, he studied law, served in the Continental Congress (1775–78, 1782–83, and 1785–87), and was one of the justices of the United States Supreme Court from 1789 until his death. Wilson's reputation as an able lawyer has been growing of late, and hardly any member of the convention ranks higher than he for profound insight into the real nature of the government and constitution of the United States.—GEORGE WYTHE was born in Elizabeth county, Va., in 1726, and died at Richmond, Va., June 8, 1806. He was educated at William and Mary College, studied law, and was a member of the Virginia legislature from 1768, and of the Continental Congress in 1775. He was chancellor of his State from 1778 until 1798.

¹ The following were some of the members of the convention not elsewhere noticed.—OLIVER ELLSWORTH was born at Windsor, Conn., April 29, 1745, and died at his birthplace Nov. 26, 1807. He graduated at Princeton College in 1766, became a lawyer, and judge of the superior court of his State, and in 1796 was appointed chief justice of the United States Supreme Court. He was sent on a mission to France in 1799, and resigned his place as chief justice in 1800.—ELBRIDGE GERRY was born at Marblehead, Mass., July 17, 1744, and died at Washington, Nov. 23, 1814. He graduated at Harvard College in 1762, was a member of the Continental Congress, 1776–1780 and 1783–1785, and of the Congress under the constitution, 1789–1793. He was elected vice-president by the Democratic party in 1812, and died in office.—RUFUS KING was born at Scarborough, Mass. (now Maine), March 24, 1755, and died at Jamaica,

senting the people of the whole State, according to population, and the other giving an equal representation to the towns. They proposed that the new Congress should be made up of two houses, one representing the States in proportion to their population, the other giving an equal vote to each State. At a dead-lock, the convention referred the proposition to a committee, and it reported in favour of the Connecticut compromise. Connecticut had been voting in the large-State list, and the votes of her delegates could not be spared from their slender majority; now another of the large States, North Carolina, came over to Connecticut's proposal, and it was adopted. Thus the first great struggle of the convention resulted in a compromise, which took shape in the peculiar feature of the constitution, the senate.

The
work of
the con-
vention.

105. The little States were still anxious, in every new question, to throw as much power as possible into the hands of their special representative, the senate; and that body thus obtained its power to act as an executive council as a restraint on the president in appointments and treaties. This was the only survival of the first alignment of parties; but new divisions arose on almost every proposal introduced. The election of the president was given at various times to Congress and to electors chosen by the State legislatures; and the final mode of choice, by electors chosen by the States, was settled only two weeks before the end of the convention, the office of vice-president coming in with it. The opponents and supporters of the slave trade compromised by agreeing not to prohibit it for twenty years. Another compromise included three-fifths of the slaves in enumerating population for representation. This was the provision which gave the slave-holders abnormal power as the number of slaves increased; for a district in the "black belt" of the South, while three-fifths of its slaves were enumerated, really gave representation to its few whites only.

106. Any explanation of the system introduced by the constitution must start with the historical fact that, while the national government was practically suspended, from 1776 until 1789, the only power to which political privileges had been given by the people was the States, and that the State legislatures were, when the convention met, politically omnipotent, with the exception of the few limitations imposed on them by the early State constitutions, which were not at all so searching or severe as those of more recent years. The general rule, then, is that the Federal Government has only the powers granted to it by the Federal constitution, while the State has all governmental powers not forbidden to it by the State or the Federal constitution. But the phrase defining the Federal Government's powers is no longer "expressly granted," as in the Articles of Confederation, but merely "granted," so that powers necessary to the execution of granted powers belong to the Federal Government, even though not directly named in the constitution. This question of the interpretation, or "construction," of the constitution is at the bottom of real national politics in the United States: the minimizing parties have sought to hold the Federal Government to a strict construction of granted powers, while their opponents have sought to widen those powers by a broad construction of them. The strict-construction parties, when they have come into power, have regularly adopted the practice of their opponents, so that construction has pretty steadily broadened; the power to "regulate commerce between the States" is now interpreted so as to include the power of Congress to regulate the fares and contracts of railways engaged in inter-State commerce (§ 327), which would have been deemed preposterous in 1787.

The
consti-
tution.

107. Popular sovereignty, then, is the basis of the American system. But it does not, as does the English system, clothe its legislative body and leave unlimited powers to it. It makes its "constitution" the permanent medium of its orders or prohibitions to all branches of the Federal Government and to many branches of the State Governments: they must do what the constitution directs and leave undone what it forbids. The people, therefore, are continually laying their commands on their Governments; and they have instituted a system of Federal courts to ensure obedience to their commands. An English court must obey the Act of Parliament; the American court is bound and sworn to obey the constitution first, and the Act of Congress or of the State legislature only so far as it is warranted by the constitution. But the American court does not deal directly with the Act in question;

it deals with individuals who have a suit before it. One of these individuals relies on an Act of Congress or of a State legislature; the Act thus comes before the court for examination; and it supports the Act or disregards it as "unconstitutional," or in violation of the constitution. If the court is one of high rank or reputation, or one to which a decision may be appealed, as the United States Supreme Court, other courts follow the precedent, and the law falls to the ground. The court does not come into direct conflict with the legislative body; and, where a decision would be apt to produce such a conflict, the practice has been for the court to regard the matter as a "political question" and refuse to consider it.

108. The preamble states that "we, the people of the United States," establish and ordain the constitution. Events have shown that it was the people of the whole United States that established the constitution, but the people of 1787 seem to have inclined to the belief that it was the people of each State for itself. This belief was never changed in the South; and in 1861 the people of that section believed that the ordinances of secession were merely a repeal of the enacting clause by the power which had passed it, the people of the State.

109. The original constitution was in seven articles. The first related to the organization and powers of Congress, which consists of a senate and house of representatives. Representatives are to be inhabitants of the State for which they are chosen, to be twenty-five years old at least, and are to serve two years. Each house of representatives thus lasts for two years, and this period is usually known as "a Congress"; the fiftieth Congress will expire March 4, 1889, having completed the first century of the constitution. Representatives are assigned to the States in proportion to population, and this fact forced the provision for a decennial census, the first appearance of such a provision in modern national history. The first census was taken in 1790. Apportionment of representatives from 1883 until 1893 is governed by the census of 1880; by Act of Congress the number 154,325 is the divisor into a State's population which fixes the number of the State's representatives, the whole number of representatives being 325, with eight delegates from the Territories, having seats and the right to debate but not to vote. The house elects its speaker and other officers, and has the power of impeachment.

110. The legislature of each State elects two senators, to serve for six years; and no State can ever be deprived of its equal share of representation except by its own consent. The senators are divided into three classes, the term of one class expiring every two years. Six years are therefore necessary to completely change the composition of the senate, and it is considered a continuous body. Senators are to be at least thirty years old, and must be inhabitants of the States from which they are chosen and citizens of the United States for at least nine years previous to their election. The vice-president presides over the senate, having no vote unless in case of an equal division. But the legislative provision (continuing until 1887) that the death or disability of the president and vice-president devolved the office of president on the presiding officer *pro tempore* of the senate made that officer one of great possible importance, and the vice-president regularly retired just before the end of a session, so that a *pro tempore* officer might be selected (§ 117).

111. All officers of the United States are open to impeachment by the house of representatives, the impeachment to be tried by the senate, and the penalty to be no more than removal and disqualification to serve further under the United States. When the president is tried, the chief justice of the Supreme Court presides.

112. The members of both houses are privileged from arrest and from being questioned elsewhere for words spoken in debate. Each house passes on the election of its own members; but an Act of Congress may control the Acts of the State legislature as to time, place, and manner of elections, except as to the place of choosing senators, in which the legislature remains supreme. Congress has exercised the power by passing a general election law. The two houses cannot adjourn to another place, or for more than three days, unless by common consent. Their members are paid by the United States, and must not be office-holders or receive any office created or increased in pay during their term of service in Congress.

113. When a bill passes both houses it goes to the president. Veto If he signs it becomes law. If he holds it without signing for ten days (Sundays excepted) it becomes law, unless the final adjournment of Congress comes in the ten days. All bills passed in the last ten days of a Congress are therefore at the mercy of the president; he can prevent them from becoming laws by simply retaining them. If the president decides to veto a bill he returns it, with a statement of his objections, to the house in which it originated. It can then only become law by the vote of two-thirds of both houses.

114. The powers of Congress are fully stated. The first is to "lay and collect taxes, duties, imposts, and excises, [in order] to pay the debts and provide for the common defence and general welfare of the United States." The words in brackets are not in

the original, but they are included in construction by all respectable authorities, as essential to its meaning; any other construction would give Congress absolute power over whatever it thought to be for "the common defence or general welfare." Duties, &c., are to be uniform throughout the United States. Other powers are—to borrow money; to regulate foreign and domestic commerce; to make rules for naturalization, and bankruptcy laws; to coin money, regulate the value of foreign coins, and fix the standard of weights and measures; to punish the counterfeiting of Federal securities and current coin; to establish post-offices and post-roads; to establish patent and copyright systems; to establish courts inferior to the supreme court; to punish offences on the high seas or against international law; to declare war, grant letters of marque and reprisal, and make rules for captures; to raise and support armies, no appropriation to be for more than two years; to provide and maintain a navy; to make articles of war; to use the militia of the States in executing Federal laws, suppressing insurrections, and repelling invasions; to provide for organizing, arming, and disciplining this militia, leaving the States to appoint the officers and carry out the system; to establish a national capital or Federal district (the District of Columbia, containing the city of Washington), and to exercise exclusive powers of legislation over it, and over sites for forts, dockyards, &c., bought by permission of the States; and, finally, "to make all laws which shall be necessary and proper for carrying into execution the foregoing powers, and all other powers vested by this constitution in the Government of the United States, or in any department or office thereof." This last power has been the subject of most debate. It was urged that, unless an Act of Congress was strictly "necessary" for the execution of one of the granted powers, it was invalid. The Supreme Court has held that the Act need not be "absolutely necessary," or even "very necessary,"—that it is enough if it is "necessary." As the decision of the necessity is with the legislative body, the word opens a wide sweep for construction; but it has always furnished a barricade which the opponents of a bill have often found very strong.

Powers forbidden to the Federal Government;

115. The real sovereignty which made the constitution shows itself in a double series of prohibitions—on the Federal Government and on the States. The Federal Government shall not suspend the privilege of the writ of *habeas corpus* except in case of rebellion or invasion, when the public safety requires it. Since the Civil War the Supreme Court has decided that the writ itself can never be suspended while the courts are open, that the Federal Government may suspend the *privilege* of the writ as to classes of persons directly interested in the war, but that the writ is still to issue and the court to decide whether the applicant comes within the excepted classes or not. Congress must not pass any bill of attainder or *ex post facto* law, tax exports, give commercial preference to the ports of one State over those of another, lay direct taxes except in proportion to census population, or grant any title of nobility. Money is to be taken from the treasury only in consequence of appropriations made by law. And no person in the service of the United States may accept any gift or title from a foreign power without consent of Congress.

to the States.

116. The States are absolutely forbidden to make treaties of any kind, to grant letters of marque and reprisal, to coin money, to emit bills of credit, to make anything but silver a legal tender, to grant any title of nobility, to pass any bill of attainder, *ex post facto* law, or law impairing the obligation of contracts. It follows from the last clause that States cannot pass bankruptcy laws. The States are forbidden, except by consent of Congress, to lay any duties on imports or exports, except inspection charges, to be paid into the Federal treasury; to lay any tonnage duties; to keep troops (a word which does not cover militia) or ships in peace; to make any agreement with another State or with a foreign power; or to engage in war unless actually invaded.

The president and his powers.

117. The president is to be a native citizen, at least thirty-five years old, and at least fourteen years a resident within the United States. He is paid by the United States; and his salary is not to be increased or diminished by Congress during his term: the Act must apply to the successors of the president who signs the Act. He is sworn to execute his office faithfully, and to "preserve, protect, and defend the constitution of the United States." In case of his death, resignation, or inability (by impeachment or otherwise) the vice-president succeeds him; and, in case of the inability of both, the members of the cabinet succeed in a prescribed order, according to the Presidential Succession Act of 1886. The president has the veto power already described, sends messages to Congress on the state of the Union or on special subjects, convenes either house or both on extraordinary occasions, receives foreign envoys, commissions officers of the United States, and oversees the execution of the laws passed by Congress. He makes treaties; but no treaty is valid unless passed by the senate by a two-thirds vote of those present. He appoints ministers and consuls, judges, and all other officers whose appointment Congress has not vested in other officers; but presidential appointments must be confirmed by the senate, though the president may make temporary appointments

during the recess of the senate, to hold until the end of their next session. He is commander-in-chief of the army and navy, and has power of pardon or reprieve for offences against Federal laws, except in case of impeachment. And he may call upon heads of departments for an opinion in writing on any subject relating to his department.

118. The last clause has evolved the "cabinet," a term not known in the constitution. When Congress has by law organized cabinet, a department, its leading officer is called its secretary. There are now (1887) seven departments,—those of state, of the treasury, of war, of the navy, of the post-office, of the interior, and of justice; and departments of agriculture and of labour have been proposed. The secretaries are selected by the president and are confirmed by the senate, but are not responsible to any one but the president. Nor is he bound by their individual opinions, or even by an unanimous opinion from one of their periodical meetings. They are his advisers only.

119. The people have no direct voice in the choice of president The electors and vice-president: they choose electors, each State having as total many electors as it has senators and representatives together; system. and the electors choose the president and vice-president, meeting at their State capitals for that purpose, and sending separate certificates of their choice of president and of vice-president to the presiding officer of the senate at Washington. The electors are to be chosen in such manner as the legislature of each State shall direct; and this plenary power of the legislatures was the source of the unhappy disputed election of 1876-77. By Acts of Congress, the electors are to be chosen on the Tuesday after the first Monday of November; they meet in their States and vote on the first Wednesday of December; and Congress meets on the second Wednesday of February to witness the counting of the electoral votes. The electors are legally State officers; and the action of their States in regard to them was evidently intended to be final. Until 1887 Congress refused to provide for necessary proof of the State's action, and claimed the power to provide from time to time for emergencies. Such emergencies were constantly occurring; and Congress, which was meant to be merely a witness of the count by the presiding officer of the senate, had seized, before 1876, a general supervisory power over the electors and their votes. This illegitimate function of Congress broke down in 1876-77, for several Southern States sent different sets of certificates; the two houses of Congress were controlled by opposite parties, and could agree on nothing; and an extra-constitutional machine, the "electoral commission," was improvised to tide over the difficulty. Now provision is made by the Electoral Count Act of 1887 for the State's certification of its votes; and the certificate which comes in legal form is not to be rejected but by a vote of both houses. If there is no majority of electoral votes for any person for vice-president, the senate, by a majority of its members, chooses from the two names highest on the list. If there is no majority for president, the house of representatives chooses one from the three names highest on the list, each State having one vote.

120. The electors were meant to exercise a perfect freedom of Powers choice, and there are instances in early years of electors voting for of the personal friends of the opposite party. It was originally provided that each elector was to name two persons, without specifying which was to be president or vice-president. When the votes were counted, the highest name on the list, if it had a majority of all the votes, obtained the presidency, and the next highest became vice-president. It has been said that the convention cut out the office of president according to the measure of George Washington, and there was no difficulty while he served: each elector cast one of his votes for Washington, and he was chosen unanimously; the struggle was for the second office. When he went out of office in 1796 the parties began to name candidates in advance for the two offices; the electors began to feel bound to vote for their party candidates; and the individuality of the electors disappeared at once. In the election of 1800 the electors of the successful party voted together like a well-drilled army, and the result was that the two candidates of the successful party had an equal vote. The defeated party controlled the house of representatives, and their efforts to choose Burr president instead of Jefferson exasperated the Democrats and sealed the fate of the old system. An amendment to the constitution was adopted in 1804, changing the method of amending the electors in voting, so that each should vote separately for the ment. two offices and thus prevent any tie vote from this cause.

121. The constitution provides for one Supreme Court, having The original jurisdiction in cases affecting foreign ministers and con- Federal suls, and those to which a State shall be a party, and appellate courts. jurisdiction from such subordinate courts as Congress should from time to time establish. All judges were to hold office during good behaviour (§ 237), and their salaries were not to be diminished during their continuance in office. Criminal trials were to be by jury, except in impeachments, and were to be held within the State in which the offence had been committed, or in places assigned by law for the trial of offences committed outside the jurisdiction of any State. The whole jurisdiction of Federal courts, covering both

the original and the appellate jurisdiction of the Supreme Court, was clearly stated. Federal courts were to deal with all cases in law or equity arising under the constitution or the laws or treaties made under it; with all cases affecting public ministers and consuls, or admiralty or maritime law; with suits by or against the United States; and with suits by one State against another, by a State against citizens of another State, by a citizen of one State against a citizen of another, by a citizen of a State against citizens of his own State when the question was one of a grant of land from different States, by a State or its citizens against foreigners, or by a foreigner against an American. As the section first stood, it was open to the construction of giving the power to the citizen of one State to sue another State, and the Supreme Court so construed it in 1793-94. The States at once took the alarm; and the 11th amendment, forbidding suit against a State under this section except by another State, was ratified in 1798.

Organi-
zation
of the
judiciary.

122. As soon as the new Government was organized in 1789, a Judiciary Act was passed, organizing the whole system of inferior Federal courts. Subsequent development has not changed the essential nature of this first Act. The Supreme Court now consists of a chief justice and eight associate justices; there are nine circuit courts, each consisting of a Supreme Court justice and a circuit judge; and fifty-six district courts, each with a district judge. Each circuit comprises several States; and the Supreme Court justices, in addition to their circuit work, meet in bank annually at Washington. The districts cover each a State or a part of a State. Appeal lies from the district to the circuit court when the matter involved is of a value greater than \$500, and from the circuit to the Supreme Court when \$5000 or more is involved. There are also Territorial courts; but these are under the absolute power of Congress over the Territories, and are not covered by the constitutional provisions as to courts. Consular courts, held abroad, fall under the treaty power.

Its power
over indi-
viduals.

123. The Constitution's leading difference from the Confederation is that it gives the national Government power over individuals. The Federal courts are the principal agent in securing this essential power; without them, the constitution might easily have been as dismal a failure as the Confederation. It has also been a most important agent in securing to the national Government its supremacy over the States. From this point of view the most important provision of the constitution is the grant of jurisdiction to Federal courts in cases involving the construction of the constitution or of laws or treaties made under it. The 25th section of the Judiciary Act permitted any Supreme Court justice to grant a writ of error to a State court in a case in which the constitutionality of a Federal law or treaty had been denied, or in which a State law objected to as in violation of the Federal constitution had been maintained. In such cases, the defeated party had the right to carry the "Federal question" to the Federal courts. It was not until 1816 that the Federal courts undertook to exercise this power; it raised a storm of opposition, but it was maintained, and has made the constitution what it professed to be—"the supreme law of the land." As a subsidiary feature in the judiciary system, treason was restricted to the act of levying war against the United States, or of adhering to their enemies, giving them aid and comfort; the evidence of it to confession in open court, or to the testimony of two witnesses to an overt act; and any forfeiture in the punishment to a life effect only. The States, however, have always asserted their power to punish for treason against them individually. It has never been fully maintained in practice; but the theory had its effect in the secession period.

Treason.

Fugitive
criminals
and
slaves.

124. The States were bound to give credit to the public records of other States, to accord citizenship to the citizens of other States, to return criminals fleeing from other States, and to return "persons held to service or labour" under the laws of another State. This last was the "fugitive slave" provision of the constitution, which became so important after 1850 (§ 228).

Guar-
antee
clause.

125. The Federal Government was to guarantee a republican form of government to each of the States, and to protect each of them against invasion, or, on application of the legislature or governor, against domestic violence. The "guarantee clause" really substituted State rights under the guarantee of the Federal Government for the notion of State sovereignty under the guarantee of the State itself. A still stronger case of this was in the 5th article of the constitution, stating the manner of amendment. The convention of 1787, it must be borne in mind, was working under a system of government which provided expressly that it was not to be altered in the least unless by consent of all the States. The constitution provided that it was to go into force, so far as the ratifying States were concerned, as soon as nine of the thirteen States should ratify it, and that any future amendment, when passed by two-thirds of both houses and ratified by the legislatures or conventions of three-fourths of the States, should become a part of the constitution. By application of the legislatures of two-thirds of the States, a new convention, like that which framed the constitution, might take the place of the two houses of Congress in proposing amendments. A system under

which a State submits its whole future destiny to an unlimited power of decision in three-fourths of its associate States can hardly be called one of State sovereignty.

126. The debts of the Confederation, and its engagements, were Supreme made binding on the new Government; the constitution, and law of laws and treaties to be made under it, were declared to be "the the land. supreme law of the land"; judges of State courts were to be bound thereby, "anything in the constitution or laws of any State to the contrary notwithstanding"; all the legislative, executive, and judicial officers of the United States and of each and every State were to be bound by oath or affirmation to support the constitution of the United States; but religious tests were forbidden.

127. Ten amendments were adopted so soon after the ratification of the constitution that they may fairly be considered a part of ten the original instrument. They were due to a general desire that amend- a "bill of rights" of some kind should be added to it; but they ments. did not alter any of the articles of the constitution. They forbade any establishment of religion by Congress, or any abridgment of freedom of worship, of the press, or of speech, or of the popular right to assemble and petition the Government for redress of grievances; the billeting of soldiers; unreasonable searches or seizures, or general warrants; trials for infamous crimes except through a grand jury's action; subjecting a person for the same offence to be twice put in jeopardy of life or limb; compelling him to witness against himself in criminal cases; the taking of life, liberty, or property without due process of law or without compensation for property; and the demand of excessive bail, or the imposition of excessive fines or of cruel or unusual punishments. They asserted the right of the people to keep and bear arms, to a jury trial from the vicinage in criminal cases or in cases involving more than \$20, to a copy of the indictment, to the testimony against the prisoner, to compulsory process on his behalf, and to counsel for him. And they stated expressly the general principle already given, that the Federal Government is restricted to granted powers, while those not mentioned are reserved "to the States respectively or to the people."

128. The omission of the word "thereof" after the clause last mentioned seems significant. The system of the United States reignty. is almost the only national system, in active and successful operation, as to which the exact location of the sovereignty is still a mooted question. The contention of the Calhoun school—that the separate States were sovereign before and after the adoption of the constitution, that each State adopted it by its own power, maintained it by its own power, and could put an end to it by its own power, that the Union was purely voluntary, and that the whole people, or the people of all the other States, had no right to maintain or enforce the Union against any State—has been ended by the Civil War. But that did not decide the location of the sovereignty. The prevalent opinion is still that first formulated by Madison:—that the States were sovereign before 1789; that they then gave up a part of their sovereignty to the Federal Government; that the Union and the constitution were the work of the States, not of the whole people; and that reserved powers are reserved to the people of the States, not to the whole people. The use of this bald phrase "reserved to the people," not to the people of the several States, in the 10th amendment, seems to argue an underlying consciousness, even in 1789, that the whole people of the United States was already a political power quite distinct from the States, or the people of the States; and the tendency of later opinion is in this direction. It must be admitted that the whole people has never acted in a single capacity; but the restriction to State lines seems to be a self-imposed limitation by the national people, which it might remove, as in 1789, if an emergency should make it necessary. The Civil War amendments are considered below (§ 305-309).

129. By whatever sovereignty the constitution was framed and Details imposed, it was meant only as a scheme in outline, to be filled up of the afterwards, and from time to time, by legislation. The idea is system. most plainly carried out in the Federal judiciary: the constitution only directs that there shall be a Supreme Court, and marks out the general jurisdiction of all the courts, leaving Congress, under the restriction of the president's veto power, to build up the system of courts which shall best carry out the design of the constitution. But the same idea is visible in every department, and it has carried the constitution safely through a century which has radically altered every other civilized government. It has combined elasticity with the limitations necessary to make democratic government successful over a vast territory, having infinitely diverse interests, and needing, more than almost anything else, positive opportunities for sober second thought by the people. A sudden revolution of popular thought or feeling is enough to change the house of representatives from top to bottom; it must continue for several years before it can make a radical change in the senate, and for years longer before it can carry this change through the judiciary, which holds for life; and all these changes must take place before the full effects upon the laws or constitution

are accomplished. But the minor changes which are essential to an accommodation with the growth and development of a great nation are reached in the meantime easily and naturally in the course of legislation, to which the skeleton outline of the constitution lends itself kindly. The members of the convention of 1787 showed their wisdom most plainly in not trying to do too much; if they had done more they would have done far less.

Submis-
sion to
Congress.

130. The convention adjourned 17th September 1787, having adopted the constitution. Its last step was a resolution that the constitution be sent to the Congress of the Confederation, with the recommendation that it be submitted to conventions elected by the people of each State for ratification or rejection; that, if nine States should ratify it, Congress should appoint days for the popular election of electors, for the choice of president and vice-president by the electors, and for the meeting of senators and representatives to be chosen under the new plan of government; and that then the new Congress and president should "without delay, proceed to execute this constitution." Congress, having received the report of the convention, resolved that it be sent to the several legislatures, to be submitted to conventions; and this was all the approval the constitution ever received from Congress. Both Congress and the convention were careful not to open the dangerous question, How was a government which was not to be changed but by the legislatures of all the States to be entirely supplanted by a different system through the approval of conventions in three-fourths of them? They left such questions to be opened, if at all, in the less public forum of the legislatures.

Federal-
ists and
Anti-
federal-
ists.

131. Before the end of the year Delaware, Pennsylvania, and New Jersey had ratified; and Georgia, Connecticut, and Massachusetts followed during the first two months of 1788. Thus far the only strong opposition had been in Massachusetts, a "large State." In it the struggle began between Federalists and Antifederalists, between the friends and the opponents of the constitution, with its introduction of a strong Federal power; and it raged in the conventions, legislatures, newspapers, and pamphlets. The best of the last was *The Federalist*, written mainly by Hamilton, with the assistance of Madison and Jay, explaining the new constitution and defending it. As it was written before the constitution went into force, it speaks much for the ability of its writers that it has passed into a standard text-book of American constitutional law.

Ratifica-
tion.

132. The seventh and eighth States—Maryland and South Carolina—ratified in April and May 1788; and, while the conventions of Virginia and New York were still wrangling over the great question, the ninth State, New Hampshire, ratified, and the constitution passed out of theory into fact. This left the other States in an unpleasant position. The Antifederalists of the Virginia and New York conventions offered conditional ratifications of all sorts; but the Federalists stubbornly refused to consider them, and at last, by very slender majorities, these two States ratified. North Carolina refused to ratify the constitution, and Rhode Island refused even to consider it (§ 145). Congress named the first Wednesday of January 1789 as the day for the choice of electors, the first Wednesday in February for the choice of president and vice-president, and the first Wednesday in March for the inauguration of the new Government at New York city. The last date fell on the 4th of March, which has been the limit of each president's term since that time.

Inaugu-
ration.

Fall of
the Con-
federation.

133. When the votes of the electors were counted before Congress, it was found that Washington had been unanimously elected president, and that John Adams, standing next on the list, was vice-president. Long before the inauguration the Congress of the Confederation had expired of mere inanition; its attendance simply ran down

until (October 21, 1788) its record ceased, and the United States got on without any national Government for nearly six months. The struggle for nationality had been successful, and the old order faded out of existence.

134. The first census (1790) followed so closely upon the inauguration of the constitution that the country may fairly be said to have had a population of nearly four millions in 1789. Something over half a million of these were slaves, of African birth or blood. Slavery of this sort had taken root in all the colonies, its original establishment being everywhere by custom, not by law. When the custom had been sufficiently established statutes came in to regulate a relation already existing. Indented servants came only for a term of years, and then were free. Slaves were not voluntary immigrants: they had come as chattels, not as persons, and had no standing in law, and the law fastened their condition on their children. But it is not true, as the Dred Scott decision held long afterwards (§ 249), that the belief that slaves were chattels simply, things not persons, held good at the time of the adoption of the constitution. Times had changed somewhat. The peculiar language of the constitution itself, describing slaves as "persons held to service or labour, under the laws of any State," puts the general feeling exactly: they were persons from whom the laws of some of the States withheld personal rights for the time. In accordance with this feeling most of the Northern States were on the high road towards abolition of slavery. Vermont had never allowed it. In Massachusetts it was swept out by a summary court decision that it was irreconcilable with the new State constitution. Other States soon began systems of gradual abolition, which finally extinguished slavery north of Virginia, but so gradually that there were still 18 apprentices for life in New Jersey in 1860, the last remnants of the former slave system. In the new States north of the Ohio slavery was prohibited by the Ordinance of 1787 (§ 96), and the prohibition was maintained in spite of many attempts to get rid of it and introduce slavery.

Slavery
in the
United
States.

Abolition
in the
North.

135. The sentiment of thinking men in the South was exactly the same, or in some cases more bitter from their personal entanglement with the system. Jefferson's language as to slavery is irreconcilable with the chattel notion; no abolitionist agitator ever used warmer language than he as to the evils of slavery; and the expression, "our brethren," used by him of the slaves, is conclusive. Washington, Mason, and other Southern men were as warm against slavery as Jefferson, and societies for the abolition of slavery were very common in the South. No thinking man could face with equanimity the future problem of holding a separate race of millions in slavery. Like most slave laws, the laws of the Southern States were harsh: rights were almost absolutely withheld from the slave, and punishments of the severest kind were legal; but the execution of the system was milder than its legal possibilities might lead one to imagine. The country was as yet so completely agricultural, and agriculture felt so few of the effects of large production and foreign commerce, that Southern slavery kept all the patriarchal features possible to such a system.

Feeling
in the
South.

136. Indeed, the whole country was almost exclusively agricultural, and, in spite of every effort to encourage manufactures by State bounties and colonial protection, they formed the meagrest element in the national production. Connecticut, which now teems with manufactures, was just beginning the production of tinware and clocks; Rhode Island and Massachusetts were just beginning to work in cotton from models of jennies and Arkwright machinery surreptitiously obtained from England after several failures and in evasion of penal Acts of Parlia-

Agricul-
ture, com-
merce,
and manu-
factures.

ment; and other States, beyond local manufactures of paper, glass, and iron, were almost entirely agricultural, or were engaged in industries directly dependent on agriculture. Commerce was dependent on agriculture for exports; and manufactured imports were enough to drown out every other form of industry.

Changes
since
1790.

137. There were but four cities in the United States having a population of more than 10,000,—Philadelphia (42,000), New York (33,000), Boston (18,000), and Baltimore (13,000). The population of the city of New York and its dependencies is now more than half as large as that of the whole United States in 1789; the State of New York or of Pennsylvania has now more inhabitants than the United States in 1790; and the new States of Ohio and Illinois, which had hardly any white inhabitants in 1789, do not fall far behind. Imports have swollen from \$23,000,000 to \$650,000,000, exports from \$20,000,000 to \$700,000,000, since 1790. The revenues of the new Government in 1790 were \$4,000,000; they have now grown to \$300,000,000 or more. The expenditures of the Government, excluding interest on the public debt, were but \$1,000,000 in 1790, where now they are \$200,000,000 or upwards per annum. It is not easy for the modern American to realize the poverty and weakness of his country at the inauguration of the new system of government, however he may realize the simplicity of the daily life of its people. Even the few large cities were but larger collections of the wooden houses, with few comforts, which composed the villages; the only advantage of their inhabitants over those of the villages was in the closer proximity to their neighbours; and but a little over 3 per cent. of the population had this advantage, against about 25 per cent. in 1880.

Communi-
cation.

138. Outside the cities communication was slow. One stage a week was enough for the connexion between the great cities; and communication elsewhere depended on private conveyance. The great rivers by which the continent is penetrated in every direction were with difficulty ascended by sailing vessels or boats; and the real measure of communication was thus the daily speed of a man or a horse on roads had beyond present conception. The western settlements were just beginning to make the question more serious. Enterprising land companies were the moving force which had impelled the passage of the Ordinance of 1787; and the first column of their settlers was pouring into Ohio and forming connexion with their predecessors in Kentucky and Tennessee. Marietta and Cincinnati (at first a Government fort, and named after the society of the Cincinnati) had been founded. But the intending settlers were obliged to make the journey down the Ohio river from Pittsburgh in bullet-proof flat-boats, for protection against the Indians, and the return trip depended on the use of oars. For more than twenty years these flat-boats were the chief means of river commerce in the west; and, in the longer trips, as to New Orleans, the boats were generally broken up at the end and sold for lumber, the crew making the trip home on foot or on horseback. John Fitch and others were already experimenting on what was soon to be the steamboat (§ 167); but the statesman of 1789, looking at the task of keeping under one Government a country of such distances, with such difficulties of communication, may be pardoned for having felt anxiety as to the future. To almost all thinking men of the time the constitution was an experiment, and the unity of the new nation a subject for very serious doubt.

Litera-
ture.

139. The comparative isolation of the people everywhere, the lack of books, the poverty of the schools and newspapers, were all influences which worked strongly against any pronounced literary development. Poems, essays, and paintings were feeble imitations of European

models; history was annalistic, if anything; and the drama hardly existed. In two points the Americans were strong, and had done good work. Such men as Jonathan Edwards had excelled in various departments of theology, and American preaching had reached a high degree of quality and influence; and, in the line of politics, the American state-papers rank among the very best of their kind. Having a very clear perception of their political purposes, and having been restricted in study and reading to the great masters of pure and vigorous English, and particularly to the English translators of the Bible, the American leaders came to their work with an English style which could hardly have been improved. The writings of Franklin, Washington, the Adamses, Hamilton, Jefferson, Madison, Jay, and others show the secret of their strength in every page. Much the same reasons, with the influences of democracy, brought oratory, as represented by Patrick Henry, Fisher Ames, John Randolph, and others, to a point not very far below the mark afterwards reached by Daniel Webster. The effect of these facts on the subsequent development of the country is not often estimated at its full value. All through an immigration of every language and dialect under heaven the English language has been protected in its supremacy by the necessity of going back to the "fathers of the republic" for the first, and often the complete, statement of principles in every great political struggle, social problem, or lawsuit.

140. The cession of the "north-west territory" by Virginia and New York had been followed up by similar cessions by Massachusetts (1785), Connecticut (1786), and South Carolina (1787). North Carolina did not cede Tennessee until late in 1789, nor Georgia her western claims until 1802. Settlement in all these regions was hardly advanced beyond what it had been at the outbreak of the revolution. The centres of western settlement, in Tennessee and Kentucky, had merely become more firmly established, and a new one, in Ohio, had just been begun. The whole western limits of settlement of the old thirteen States had moved much nearer their present boundaries; and the acquisition of the western title, with the liberal policy of organization and government which had been begun, was to have its first clear effects during the first decade of the new Government. Almost the only obstacle to its earlier success had been the doubts as to the attitude which the Spanish authorities, at New Orleans and Madrid, would take towards the new settlements. They had already asserted a claim that the Mississippi was an exclusively Spanish stream from its mouth up to the Yazoo, and that no American boat should be allowed to sail on it. To the western settler the Alleghanies and bad roads were enough to cut him off from any other way to a market than down the Mississippi; and it was not easy to restrain him from a forcible defiance of the Spanish claim. The Northern States were willing to allow the Spanish claim in return for a commercial treaty; the Southern States and the western settlers protested angrily; and once more the spectre of dissolution appeared, not to be laid again until the new Government had made a treaty with Spain in 1795, securing common navigation of the Mississippi.

settle-
ment.

The Mis-
sissippi
river.

141. All contemporary authorities agree that a marked Social change had come over the people since 1775, and few of them seem to think the change one for the better. Many attribute it to the looseness of manners and morals introduced by the French and British soldiers; others to the general effects of war; a few, Tories all, to the demoralizing effects of rebellion. The successful establishment of nationality would be enough to explain most of it; and if we remember that the new nation had secured its title to a vast western territory, of unknown but rich capacities, which it was now moving to reduce to possession by

Social
condi-
tions.

emigration, it would seem far more strange if the social conditions had not been somewhat disturbed.

VI. THE DEVELOPMENT OF DEMOCRACY: 1789-1801.

Democracy in the United States;

142. All the tendencies of political institutions in the United States had certainly been towards democracy; but it cannot be said that the leading men were hearty or unanimous in their agreement with this tendency. Not a few of them were pronounced republicans even before 1775, but the mass of them had no great objections to a monarchical form of government until the war-spirit had converted them. The Declaration of Independence had been directed rather against *the* king than against *a* king. Even after popular sovereignty had pronounced against a king, class spirit was for some time a fair substitute for aristocracy. The obstacles to communication, which compelled the mass of the people to live a very isolated existence, gave abnormal prominence and influence to those who, by ability or wealth, could overcome these obstacles; and common feeling made these a class, with many symptoms of strong class feelings. As often happens, democracy at least thought of a Cæsar when it apprehended class control. The discontented officers of the revolutionary armies offered to make Washington king, though he put the offer by without even considering it. The suggestion of a return to monarchy in some form, as a possible road out of the confusion of the Confederation, occurs in the correspondence of some of the leading men. And while the convention of 1787 was holding its secret sessions a rumour went out that it had decided to offer a crown to an English prince.

in the States;

in the constitution.

143. The State constitutions were democratic, except for property or other restrictions on the right of suffrage, or provisions carefully designed to keep the control of at least one house of the State legislature "in the hands of property." The Federal constitution was so drawn that it would have lent itself kindly either to class control or to democracy. The electoral system of choosing the president and vice-president was altogether anti-democratic, though democracy has conquered it: not an elector, since 1796, has disobeyed the purely moral claim of his party to control his choice (§§ 119, 120). Since the senate was to be chosen by the State legislatures, "property," if it could retain its influence in those bodies, could control at least one house of Congress. The question whether the constitution was to have a democratic or an anti-democratic interpretation was to be settled in the next twelve years.

Influence of immigration.

144. The States were a strong factor in the final settlement, from the fact that the constitution had left to them the control of the elective franchise: they were to make its conditions what each of them saw fit. Religious tests for the right of suffrage had been quite common in the colonies; property tests were almost universal. The former disappeared shortly after the revolution; the latter survived in some of the States far into the constitutional period. But the desire to attract immigration was always a strong impelling force to induce States, especially frontier States, to make the acquisition of full citizenship and political rights as easy and rapid as possible. This force was not so strong at first as it was after the great stream of immigration began about 1848 (§ 236), but it was enough to tend constantly to the development of democracy; and it could not but react on the national development. In later times, when State laws allow the immigrant to vote even before the period assigned by Federal laws allows him to become a naturalized citizen, there have been demands for the modification of the ultra State democracy; but no such danger was apprehended in the first decade.

Organization of the new Government.

145. The Antifederalists had been a political party, but a party with but one principle. The absolute failure of that principle deprived the party of all cohesion; and the Federalists controlled the first two Congresses almost entirely. Their pronounced ability was shown in their organizing measures, which still govern the American system very largely. The departments of state, of the treasury, of war,

of justice, and of the post-office were rapidly and successfully organized; Acts were passed for the regulation of seamen, commerce, tonnage duties, lighthouses, intercourse with the Indians, Territories, and the militia; a national capital was selected; a national bank was chartered; the national debt was funded, and the State debts were assumed as part of it. The first four years of the new system showed that the States had now to deal with a very different power from the impotent Congress of the Confederation. The new power was even able to exert a pressure upon the two States which had not yet ratified the constitution, though, in accordance with the universal American prejudice, the pressure was made as gentle as possible. As a first step, the higher duties imposed on imports from foreign countries were expressly directed to apply to imports from North Carolina and Rhode Island. North Carolina having called a second convention, her case was left to the course of nature; and the second convention ratified the constitution (November 21, 1789). The Rhode Island legislature wrote to ask that their State might not be considered altogether foreigners, made their duties agree with those of the new Government, and reserved the proceeds for "continental" purposes. Still no further steps were taken. A bill was therefore introduced, directing the president to suspend commercial intercourse with Rhode Island, and to demand from her her share of the continental debt. This was passed by the senate, and waited but two steps further to become law. Unofficial newspaper proposals to divide up the little State between her two nearest neighbours were stopped by her ratification (May 29, 1790). All the "old thirteen" were thus united under the constitution; and yet, so strong is the American prejudice for the autonomy of the States that these last two were allowed to enter in the full conviction that they did so in the exercise of sovereign freedom of choice. Their entrance, however, was no more involuntary than that of others. If there had been real freedom of choice, nine States would never have ratified: the votes of Pennsylvania, Massachusetts, New Hampshire, Virginia, and New York were only secured by the pressure of powerful minorities in their own States, backed by the almost unanimous votes of the others.

Completion of the Union.

146. Protection was begun in the first Tariff Act, whose Hamiltonian object, said its preamble, was the protection of domestic manufactures. The duties, however, ranged only from $7\frac{1}{2}$ to 10 per cent., averaging about $8\frac{1}{2}$ per cent. The system, too, had rather a political than an economic basis. Until 1789 the States had controlled the imposition of duties. The separate State feeling was a factor so strong that secession was a possibility which every statesman had to take into account. Hamilton's object, in introducing the system, seems to have been to create a class of manufacturers, running through all the States, but dependent for prosperity on the new Federal Government and its tariff. This would be a force which would make strongly for national government, and against any attempt at secession, or against the tendency to revert in practice to the old system of control by State legislatures, even though it based the national idea on a conscious tendency towards the development of classes. The same feeling seems to have been at the bottom of his establishment of a national bank, his assumption of State debts, and most of the general scheme which his influence forced upon the Federal party.

Hamiltonian protection.

147. In forming his cabinet, Washington had paid attention to the opposing elements which had united for the temporary purpose of ratifying the constitution. The national element was represented by Hamilton, secretary of the treasury, and Knox (p. 789), secretary of war; the particularist element (using the term to indicate support of

The first cabinet.

the States, not of a State) by Jefferson, secretary of state, and Edmund Randolph, attorney-general. It was not long before the drift of opinion in cabinet meetings showed an irreconcilable divergence, on almost every subject, between these two elements, and Hamilton and Jefferson became the representatives of the two opposite tendencies which have together made up the sum of public American history. At the end of 1792 matters were in train for the general recognition of the existence of two parties, whose struggles were to decide the course of the constitution's development. The occasion came in the opening of the following year, when the new nation was first brought into contact with the French Revolution.

The Jefferson school of politics.

148. The controlling tendency of Jefferson and his school was to the maintenance of individual rights at the highest possible point, as the Hamilton school was always ready to assert the national power to restrict individual rights for the general good. Other points of difference are rather symptomatic than essential. The Jefferson school supported the States, not out of love for the States, but out of a belief that the States were the best bulwarks for individual rights. When the French Revolution began its usual course in America by agitation for the "rights of man," it met a sympathetic audience in the Jefferson party and a cold and unsympathetic hearing from the Hamilton school of Federalists. The latter were far more interested in securing the full recognition of the power and rights of the nation than in securing the individual against imaginary dangers, as they thought them. For ten years, therefore, the surface marks of distinction between the two parties were to be connected with the course of events in Europe; but the essence of distinction was not in the surface marks.

The Hamilton school.

149. The new Government was not yet four years old; it was not familiar, nor of assured permanency. The only national Governments of which Americans had had previous experience were the British Government and the Confederation: in the former they had had no share, and the latter had had no power. The only places in which they had had long-continued, full, and familiar experience of self-government were their State Governments: these were the only governmental forms which were then distinctly associated in their minds with the general notion of republican government. The governing principle of the Hamilton school, that the construction or interpretation of the terms of the constitution was to be such as to broaden the powers of the Federal Government, necessarily involved a corresponding trenching on the powers of the States (§ 106). It was natural, then, that the Jefferson school should look on every feature of the Hamilton programme as "anti-republican," meaning, probably, at first no more than opposed to the State system, as hitherto known, though, with the growth of political bitterness, the term soon came to imply something of monarchical and, more particularly, of English tendencies. The disposition of the Jefferson school to claim for themselves a certain peculiar title to the position of "republicans" soon developed into the appearance of the first Republican party, about 1793.

Party differences.

150. Many of the Federalists were shrewd and active business men, who naturally took prompt advantage of the opportunities which the new system offered. The Republicans therefore believed and asserted that the whole Hamilton programme was dictated by selfish or class interest; and they added this to the accusation of monarchical tendencies. These charges, with the fundamental differences of mental constitution, exasperated by the passion which differences as to the French Revolution seemed to carry with them everywhere, made the political history of this decade a very unpleasant record. The provision for establishing the national capital on the

Potomac (1790) was declared to have been carried by a The corrupt bargain; and accusations of corruption were renewed at every opportunity. In 1793 a French agent, Genet, appeared to claim the assistance of the United States for the French republic. Washington decided to issue a proclamation of neutrality, the first act of the kind in American history. It was the first indication, also, of the policy which has made the course of every president, with the exception of Polk (§ 223), a determined leaning to peace, even when the other branches of the Government have been intent on war. The proclamation of 1793 brought about the first distinctly party feeling; and it was intensified by Washington's charge that popular opposition in western Pennsylvania (1794) to the new excise law had been fomented by the extreme French party. Their name, Democrat, was applied by the Federalists to the whole Republican party as a term of contempt, but it was not accepted by the party for some twenty years; then the compound title "Democratic-Republican" became, as it still is, the official title of the party. There was no party opposition, however, to the re-election of Washington in 1792, or to the admission of Vermont (1791), Kentucky (1792), and Tennessee (1796) as new States. The national capital. Genet's mission. The Whisky Insurrection. Admission of Vermont, Kentucky, and Tennessee.

151. The British Government had accredited no minister to the United States, and it refused to make any commercial treaty or to give up the forts in the western territory of the United States, through which its agents still exercised a commanding influence over the Indians. In the course of its war with France, the neutral American vessels, without the protection of a national navy, fared badly. A treaty negotiated by Chief-Justice Jay (1794) settled these difficulties for the following ten years. But, as it engaged the United States against any intervention in the war on behalf of France, and as it granted some unfamiliar privileges to Great Britain, particularly that of extradition, the Republicans made it very unpopular, and the first personal attacks on Washington's popularity grew out of it. In spite of occasional Republican successes, the Federalists retained a general control of national affairs; they elected John Adams president in 1796, though Jefferson was chosen vice-president with him; and the national policy of the Federalists kept the country out of entangling alliances with any of the European belligerents. To the Republicans, and to the French republic, this last point of policy was only a practical intervention against France and against the rights of man. Jay's treaty. Election of 1796.

152. At the end of Washington's administration the French Directory, following up its successes in Germany and Italy and its exactions from conquered powers, broke off relations with the United States, demanding the abrogation of Jay's treaty and a more pronounced sympathy with France. Adams sent three envoys to endeavour to re-establish the former relations; they were met by official or unofficial demands for "money, a great deal of money," as a prerequisite to peace. They refused; their letters home were published; and the Federalists at last had the opportunity of riding the whirlwind of an intense popular desire for war with France. Intercourse with France was suspended by Congress (1798); the treaties with France were declared at an end; American frigates were authorized to capture French vessels guilty of depredations on American commerce, and the president was authorized to issue letters of marque and reprisal; and an American army was formed, Washington being called from his retirement at Mount Vernon to command it. The war never went beyond a few sea-fights, in which the little American navy did itself credit, and Napoleon, seizing power the next year, renewed the peace which should never have been broken. But the quasi-war had internal consequences to The "X. Y. Z." mission. Quasi-war with France.

the young republic which surpassed in interest all its foreign difficulties: it brought on the crisis which settled the development of the United States towards democracy.

153. The reaction in Great Britain against the indefinite "rights of man" had led parliament to pass an alien law, a sedition law suspending the writ of *habeas corpus*, and an Act giving wide and scarcely defined powers to magistrates for the dispersion of meetings to petition for redress of grievances. The Federalists were in control of a Congress of limited powers; but they were strongly tempted by sympathies and antipathies of every sort to form their programme on the model furnished from England. The measures which they actually passed were based only on that construction of the constitution which is at the bottom of all American politics; they only tended to force the constitution into an anti-democratic direction. But it was the fixed belief of their opponents that they meant to go farther,—to forget the limitations imposed by the ten-years-old constitution, and to secure their own control by some wholesale measure of political persecution.

154. Three alien laws were passed. The first raised the number of years necessary for naturalization from five to fourteen. The third permitted the arrest of subjects of any foreign power with which the United States should be at war. The second, which is usually known as the Alien Law, was limited to a term of two years; it permitted the president to arrest or order out of the country any alien whom he should consider dangerous to the country. As many of the Republican editors and local leaders were aliens, this law really put the whole Republican organization in the power of the president elected by their opponents. The Sedition Law made it a crime, punishable by fine and imprisonment, to publish or print any false, scandalous, and malicious writings against the Government of the United States, either house of Congress, or the president, with intent to defame them, or to bring them into contempt or disrepute, or to excite against them the hatred of the good people of the United States, or to stir up sedition or opposition to any lawful Act of Congress or of the president, or to aid the designs of any foreign power against the United States. In its first form the bill was even more loose and sweeping than this and alarmed the opposition thoroughly.

155. Almost all the ability of the country was in the Federalist ranks; the Republicans had but two first-rate men—Jefferson and Madison. In the sudden issue thus forced between individual rights and national power, Jefferson and Madison could find but one bulwark for the individual—the power of the States; and their use of it gave their party a permanent list to State sovereignty from which it did not recover for years. They objected to the Alien Law on the grounds that aliens were under the jurisdiction of the State, not of the Federal Government; that the jurisdiction over them had not been transferred to the Federal Government by the constitution, and that the assumption of it by Congress was a violation of the constitution's reservation of powers to the States; and, further, because the constitution reserved to every "person," not to every citizen, the right to a jury trial (§ 127). They objected to the Sedition Law on the grounds that the constitution had specified exactly the four crimes for whose punishment Congress was to provide; that criminal libel was not one of them; and that amendment I. forbade Congress to pass any law restricting freedom of speech or of the press. The Federalists asserted a common-law power in Federal judges to punish for libel, and pointed to a provision in the Sedition Law permitting the truth to be given in evidence, as an improvement on the common law, instead of a restriction on individual liberty.

156. The Republican objections might have been made

in court, on the first trial. But the Republican leaders had strong doubts of the impartiality of the Federal judges, who were Federalists. They resolved to intrench the party in the State legislatures. The Virginia legislature in 1798 passed a series of resolutions prepared by Madison, and the Kentucky legislature in the same year passed a series prepared by Jefferson. Neglected or rejected by the other States, they were passed again by their legislatures in 1799, and were for a long time the documentary basis of the Democratic party (§ 320). The leading idea expressed in both was that the constitution was a "compact" between the States, and that the powers (the States) which had made the compact had reserved the power to restrain the creature of the compact, the Federal Government, whenever it undertook to assume powers not granted to it. Madison's idea seems to have been that the restraint was to be imposed by a second convention of the States. Jefferson's idea is more doubtful; if it meant that the restraint should be imposed by any State which should feel aggrieved, his scheme was merely Calhoun's idea of nullification (§ 206); but there are some indications that he agreed with Madison.

157. The first Congress of Adams's term of office ended in 1799. Its successor, elected in the heat of the war excitement, kept the Federalist policy up to its first pitch. Out of Congress the execution of the objectionable laws had taken the shape of political persecution. Men were arrested, tried, and punished for writings which the people had been accustomed to consider quite within legitimate political methods. Some of the charges were petty, and some ridiculous. The Republican leaders made every trial as public as possible, and gained votes constantly, so that the Federalists began to be shy of the very powers which they had sought. Every new election was a storm-signal for the Federal party; and the danger was increased by the appearance of schism in their own ranks.

158. Hamilton was now a private citizen of New York; but he had the confidence of his party more largely than its nominal head, the president, and he maintained close and confidential relations with the cabinet which Adams had taken unchanged from Washington. The Hamilton faction saw no way of preserving and consolidating the newly acquired powers of the Federal Government but by keeping up and increasing the war feeling against France; Adams had the instinctive leaning of an American president towards peace. Amid cries of wrath and despair from his party he accepted the first overtures of the new Napoleonic Government, sent envoys to negotiate a peace, and ordered them to depart for France when they delayed too long. Then, discovering flat treachery in his cabinet, he dismissed it and blurted out a public expression of his feeling that Hamilton and his adherents were "a British faction." Hamilton retorted with a circular letter to his party friends, denouncing the president; the Republicans intercepted it and gave it a wider circulation than its author had intended; and the Hamilton faction tried so to arrange the electoral vote that Pinckney should be chosen president in 1800 and Adams should be shelved into the vice-presidency. Even so, the Federal party barely missed success. As things turned out, the result depended on the electoral vote of New York; and Aaron Burr (p. 788), who had introduced the drill and machinery of a modern American political party there, had made the State Republican and secured a majority for the Republican candidates. There was an effort by the Federalists to disappoint the Republicans by making Burr president; but Jefferson obtained that office, Burr becoming vice-president for four years (§ 120).

159. The "revolution of 1800" decided the future development of the United States. The new dominant

"Revolution of 1800."

party entered upon its career weighted with the theory of State sovereignty; and a civil war was necessary before this dogma, put to use again in the service of slavery, could be banished from the American system. But the democratic development never was checked. From that time the interpretation of the Federal constitution has generally favoured individual rights at the expense of governmental power. As the Republicans obtained control of the States they altered the State constitutions so as to cut out all the arrangements that favoured property or class interests, and reduced political power to the dead level of manhood suffrage. In most of the States outside of New England this process was completed before 1815; but New England tenacity was proof against the advancing revolution until about 1820. For twenty years after its downfall of 1800 the Federal party maintained its hopeless struggle, and then it faded away into nothing, leaving as its permanent memorial the excellent organization of the Federal Government, which its successful rival hardly changed. Its two successors—the Whig and the second Republican party—have been broad-constructionist parties, like the Federal party, but they have admitted democracy as well; the Whig party adopted popular methods at least, and the Republican party grew into a theory of individual rights even higher than Jefferson's,—the emancipation of enslaved labour.

The new capital.

160. The disputed election of 1800 was decided in the new capital city of Washington, to which the Government had just been removed. Its streets and parks existed only on paper. The Capitol had been begun; the White House was unfinished, and its audience room was used by Mrs Adams as a drying room for clothes; and the Congressmen could hardly find lodgings. The inconveniences were only an exaggeration of the condition of other American cities. Their sanitary conditions were so bad that yellow fever from time to time reduced them almost to depopulation. Again and again, during this decade, the fever visited Philadelphia and New York, drove out the people, and left the grass growing in the streets. The communication between the cities was still as bad as could be. The traveller was subject to every danger or annoyance that bad roads, bad carriages, bad horses, bad inns, and bad police protection could combine to inflict upon him. But the rising spirit of migration seemed to urge the people to conquer these difficulties. The first attempts were made to introduce turnpike roads and canals; and proposals were advanced for greater improvements. The war with natural obstacles had fairly begun, though it had little prospect of success until steam was brought into use as the ally of man.

The West.

161. About this time the term "the West" appears. It meant then the western part of New York State, the new territory north of the Ohio, and Kentucky and Tennessee. In settling land boundaries New York had transferred to Massachusetts, whose claims crossed her territory, the right to a large tract of land in central New York. The sale of this had carried population considerably west of the Hudson. After several American expeditions against the Ohio Indians had been defeated, another under General Anthony Wayne (1794) had compelled them to give up all the territory now in the State of Ohio. Settlement received a new impetus with increased security, and the new state of affairs added to the population of Kentucky, whose growth had been seriously checked by periodical attacks from the Indians across the Ohio. Between 1790 and 1800 the population of Ohio had risen from almost nothing to 45,000, that of Tennessee from 36,000 to 106,000, and that of Kentucky from 74,000 to 221,000,—the last-named State now exceeding five of the "old thirteen" in population. The difficulties of the western

emigrant, however, were still enormous. He obtained land of his own, fertile land and plenty of it, but little else. The produce of the soil had to be consumed at home, or near it; ready money was scarce and distant products scarcer; and comforts, except the very rudest substitutes of home manufacture, were unobtainable. The new life bore most hardly upon women; and, if the record of woman's share in the work of American colonization could be fully made up, the price paid for the final success would seem very great.

162. The number of post-offices rose during these ten Post-years from 75 to 903, the miles of post-routes from 1900 office to 21,000, and the revenue from \$38,000 to \$231,000. These figures seem small in comparison with the 55,000 post-offices, 375,000 miles of post-routes, and \$45,000,000 of revenue of 1887, but the comparison with the figures of 1790 shows a development in which the new constitution, with its increased security, must have been a factor.

163. The power of Congress to regulate patents was Patents already bearing fruit. Until 1789 this power was in the hands of the States, and the privileges of the inventor were restricted to the territory of the patenting State. Now he had a vast and growing territory within which all the profits of the invention were his own, and that development began by which human invention has been urged to its highest point, as a factor in the struggle against natural forces. Twenty patents were issued in 1793, and 22,000 ninety years afterwards; but one of the inventions of 1793, Whitney's cotton gin, has affected the history of the United States more than most of its wars or treaties.

164. When the constitution was adopted it was not Cotton known that the cultivation of cotton could be made profitable in the Southern States. The "roller gin" could clean only a half dozen pounds a day by slave labour. In 1784 eight bags of cotton, landed in Liverpool from an American ship, were seized on the ground that so much cotton could not be the produce of the United States. Eli Whitney, a Connecticut school-teacher residing in Georgia, invented the saw-gin, by which the cotton was dragged through parallel wires with openings too narrow to allow the seeds to pass; and one slave could now clean a thousand pounds a day. The exports of cotton leaped from 189,000 pounds in 1791 to 21,000,000 pounds in 1801, and doubled in three years more. The influence of this one invention, combined with the wonderful series of British inventions which had paved the way for it, can hardly be estimated in its commercial aspects. Its political influences were even wider, but more unhappy. The introduction of the commercial element into the slave system of the South robbed it at once of the patriarchal features which had made it tolerable; but, at the same time, it developed in slave-holders a new disposition to uphold and defend a system of slave labour as a "positive good." The abolition societies of the South began to dwindle as soon as the results of Whitney's invention began to be manifest.

165. The development of a class whose profits were Slavery merely the extorted natural wages of the black labourer and democracy was certain; and its political power was as certain, though it never showed itself clearly until after 1830. And this class was to have a peculiarly distorting effect on the political history of the United States. Aristocratic in every sense but one, it was ultra-Democratic (in a purely party sense) in its devotion to State sovereignty, for the legal basis of the slave system was in the laws of the several States. In time, the aristocratic element got control of the party which had originally looked to State rights as a bulwark of individual rights; and the party was finally committed to the employment of its original

doctrine for an entirely different purpose,—the suppression of the black labourer's wages.

VII. DEMOCRACY AND NATIONALITY: 1801-29.

Democracy and nationality.

166. When Jefferson took office in 1801 he succeeded to a task larger than he imagined. His party, ignoring the natural forces which tied the States together even against their wills, insisted that the legal basis of the bond was in the power of any State to withdraw at will. This was no nationality; and foreign nations naturally refused to take the American national coin at any higher valuation than that at which it was current in its own country. The urgent necessity was for a reconciliation between democracy and nationality; and this was the work of this period. An underlying sense of all this has led Democratic leaders to call the war of 1812-15 the "second war for independence"; but the result was as much independence of past ideas as of Great Britain.

Louisiana.

167. The first force in the new direction was the acquisition of Louisiana (§ 32) in 1803. Napoleon had acquired it from Spain, and, fearing an attack upon it by Great Britain, offered it to the United States for \$15,000,000. Jefferson and his party were eager to accept the offer; but the constitution gave the Federal Government no power to buy and hold territory, and the party was based on a strict construction of the constitution. Possession of power forced the strict-construction party to broaden its ideas, and Louisiana was bought, though Jefferson quieted his conscience by talking for a time of a futile proposal to amend the constitution so as to grant the necessary power. The acquisition of the western Mississippi basin more than doubled the area of the United States, and gave them control of all the great river-systems of central North America. The difficulties of using these rivers were removed almost immediately by Fulton's utilization of steam in navigation (1807). Within four years steamboats were at work on Western waters; and thereafter the increase of steam navigation and that of population stimulated one another. Population crossed the Mississippi; constantly increasing eddies filled up the vacant places to the east of the great river; and all sections of the country advanced as they had never advanced before. The "centre of population" has been carefully ascertained by the census authorities for each decade, and it represents the westward movement of population very closely. During this period it advanced from about the middle of the State of Maryland to its extreme western limit; that is, the centre of population was in 1830 nearly at the place which had been the western limit of population in 1770.

The steam-boat.

Centre of population.

The Oregon country.

168. Jefferson also laid the basis for a further acquisition in the future by sending an expedition under Lewis and Clarke to explore the territory north of the then Spanish territory of California and west of the Rocky Mountains—the "Oregon country" as it was afterwards called (§§ 221, 224). The explorations of this party (1804), with Captain Gray's discovery of the Columbia river (1792), made the best part of the claims of the United States to the country forty years later.

Election of 1804.

169. Jefferson was re-elected in 1804, serving until 1809; his party now controlled almost all the States outside of New England, and could elect almost any one whom it chose to the presidency. Imitating Washington in refusing a third term of office, Jefferson established the precedent, which has not since been violated, restricting a president to two terms, though the constitution contains no such restriction. The great success of his presidency had been the acquisition of Louisiana, which was a violation of his party principles; but all his minor successes were, like this, recognitions of the national sovereignty

which he disliked so much. After a short and brilliant naval war the Barbary pirates were reduced to submission (1805). And the authority of the nation was asserted for the first time in internal affairs. The long-continued control of New Orleans by Spain, and the persistent intrigues of the Spanish authorities, looking towards a separation of the whole western country from the United States, had been ended by the annexation of Louisiana, and they will probably remain for ever hidden in the secret history of the early West. They had left behind a dangerous ignorance of Federal power and control, of which Burr took advantage (1807). Organizing an expedition in Kentucky and Tennessee, probably for the conquest of the Spanish colony of Mexico, he was arrested on the lower Mississippi and brought back to Virginia. He was acquitted; but the incident opened up a vaster view of the national authority than democracy had yet been able to take. It had been said, forty years before, that Great Britain had long arms, but that 3000 miles was too far to extend them; it was something to know now that the arms of the Federal Government were long enough to reach from Washington city to the Mississippi.

170. All the success of Jefferson was confined to his first four years; all his heavy failures were in his second term, in which he and his party as persistently refused to recognize or assert the inherent power of the nation in international affairs. The Jay treaty expired in 1804 by limitation, and American commerce was thereafter left to the course of events, without any restriction of treaty obligations, since Jefferson refused to accept the only treaty which the British Government was willing to make. All the difficulties which followed may be summed up in a few words: the British Government was then the representative of the ancient system of restriction of commerce, and had a powerful navy to enforce its ideas; the American Government was endeavouring to force into international recognition the present system of neutral rights and unrestricted commerce, but its suspicious democracy refused to give it a navy sufficient to command respect for its ideas. Indeed, the American Government did not want the navy; it apparently expected to gain its objects without the exhibition of anything but moral force.

171. Great Britain was now at war, from time to time, with almost every other nation of Europe. In time of peace European nations followed generally the old restrictive principle of allowing another nation, like the United States, no commercial access to their colonies; but, when they were at war with Great Britain, whose navy controlled the ocean, they were very willing to allow the neutral American merchantmen to carry away their surplus colonial produce. Great Britain had insisted for fifty years that the neutral nation, in such cases, was really intervening in the war as an ally of her enemy; but she had so far modified her claim as to admit that "transshipment," or breaking bulk, in the United States was enough to qualify the commerce for recognition, no matter whether it was directed after transshipment. The neutral nation thus gained a double freight, and grew rich in the traffic; the belligerent nations no longer had commerce afloat for British vessels to capture; and the "frauds of the neutral flags" became a standing subject of complaint among British merchants and naval officers. About 1805 British prize courts began to disregard transshipment and to condemn American vessels which had made the voyage from a European colony to the mother country by way of the United States. This was really a restriction of American commerce to purely American productions, or to commerce with Great Britain direct, with the payment of duties in British ports.

172. The question of expatriation, too, furnished a good

Expatriation. many burning grievances. Great Britain maintained the old German rule of perpetual allegiance, though she had modified it by allowing the right of emigration. The United States, founded by immigration, was anxious to establish what Great Britain was not disposed to grant, the right of the subject to divest himself of allegiance by naturalization under a foreign jurisdiction. Four facts thus tended to break off friendly relations—(1) Great Britain's claim to allegiance over American naturalized subjects; (2) her claim to the belligerent right of search of neutral vessels; (3) her claim of right to impress for her vessels of war her subjects who were seamen wherever found; and (4) the difficulty of distinguishing native-born Americans from British subjects, even if the right to impress naturalized American subjects were granted. British naval officers even undertook to throw the *onus probandi* upon Americans—to consider all who spoke the English language as British subjects, unless they could produce proof that they were native-born Americans. The American sailor who lost his papers was thus open to impressment. The American Government in 1810 published the cases of such impressments since 1803, as numbering over 4000, about one-third of the cases resulting in the discharge of the impressed man; but no one could say how many cases had never been brought to the attention of a Government which never did anything more than remonstrate about them.

Orders in council. 173. In May 1806 the British Government, by orders in council, declared a blockade of the whole continent of Europe from Brest to the Elbe, about 800 miles. In November, after the battle of Jena, Napoleon answered by the "Berlin decree," in which he assumed to blockade the British Isles, thus beginning his "continental system." A year later the British Government answered by further orders in council, forbidding American trade with any country from which the British flag was excluded, allowing direct trade from the United States to Sweden only, in American products, and permitting American trade with other parts of Europe only on condition of touching in England and paying duties. Napoleon retorted with the "Milan decree," declaring good prize any vessel which should submit to search by a British ship; but this was evidently a vain fulmination.

The navy. 174. The Democratic party of the United States was almost exclusively agricultural, and had little knowledge of or sympathy with commercial interests; it had little confidence in the American navy; it was pledged to the reduction of national expenses and the debt, and did not wish to take on its shoulders the responsibility for a navy; and, as the section of country most affected by the orders in council, New England, was Federalist, and made up the active and irreconcilable opposition, a tinge of political feeling could not but colour the decisions of the dominant party. Various ridiculous proposals were considered as substitutes for a necessarily naval war; and perhaps the most ridiculous was adopted. Since the use of non-intercourse agreements as revolutionary weapons against Great Britain (§ 50), an overweening confidence in such measures had sprung up, and one of them was now resorted to—the embargo (1807), forbidding foreign commerce altogether. It was expected to starve Great Britain into a change of policy; and its effects may be seen by comparing the \$20,000,000 exports of 1790, \$49,000,000 of 1807, and \$9,000,000 of 1808. It does not seem to have struck those who passed the measure that the agricultural districts also might find the change unpleasant; but that was the result, and their complaints reinforced those of New England, and closed Jefferson's second term in a cloud of recognized misfortune. The pressure had been slightly relieved by the substitution of the Non-intercourse

Law (1809) for the embargo; it prohibited intercourse Non-in- with Great Britain and France and their dependencies, leaving other foreign commerce open; but Madison, Jefferson's successor in 1808-09, assumed in the presi- Election Law. dency a burden which was not enviable. New England of 1808. was in a ferment, and was even suspected of designs to resist the restrictive system by force (§ 180); and the administration did not feel secure enough in its position to face the future with confidence.

175. The Non-intercourse Law was to be abandoned as to either belligerent which should abandon its attacks on neutral commerce, and maintained against the other. In 1810 Napoleon officially informed the American Government that he had abandoned his system. He continued to enforce it in fact; but his official fiction served its purpose of limiting the non-intercourse for the future to Great Britain, and thus straining relations between that country and the United States still further. The elections of 1811-12 resulted everywhere in the defeat of "submission men" and in the choice of new members who were determined to resort to war against Great Britain; France had not been able to offer such concrete cases of injury as her enemy, and there was no general disposition to include her in the war. Clay, Calhoun, Crawford, and other new men seized the lead in the two houses of Congress, and forced Madison to agree to a declaration of war as a condition of his re-election in 1812. War was begun by the Election of 1812. declaration of June 18, 1812. The New England Federalists always called it "Mr Madison's war," but the president was about the most unwilling participant in it. War with England.

176. The national democracy meant to attack Great Britain in Canada, partly to gratify its Western constituency, who had been harassed by Indian attacks, asserted to have been instigated from Canada. Premonitions of success were drawn from the battle of Tippecanoe, in which Harrison had defeated the north-western league of Indians formed by Tecumseh (1811). Between the solidly settled Atlantic States and the Canadian frontier was a wide stretch of unsettled or thinly settled country, which was itself a formidable obstacle to war. Ohio had been admitted as a State in 1802, and Louisiana was admitted in 1812; but their admission had been due to the desire to grant them self-government rather than to their full development in population and resources. Cincinnati was a little settlement of 2500 inhabitants; the fringe of settled country ran not very far north of it; and all beyond was a wilderness of which little was known to the authorities. The case was much the same with western New York; the army which was to cross the Niagara river must journey almost all the way from Albany through a country far more thinly peopled than the far western Territories are in 1887. The difficulties of transport gave opportunities for speculation; and a barrel of flour sometimes reached the frontier army with its cost multiplied seven or eight fold. When a navy was to be built on the lakes, the ropes, anchors, guns, and all material had to be carried overland for a distance about equal to the length of England; and even then sailors had to be brought to man the navy, and the vessels were built of green timber: one vessel was launched nine weeks after her timber was cut. It would have been far less costly, as events proved, to have entered at once upon a naval war; but the crusade against Canada had been proclaimed all through Kentucky and the West, and their people were determined to wipe out their old scores before the conclusion of the war.

177. The war opened with disaster—Hull's surrender Disasters of Detroit; and disaster attended it for two years. Political appointments to positions in the regular army were numerous, and such officers were worse than useless. The men were not fitly trained or supplied. The war depart-

ment showed no great knowledge, and poverty put its little knowledge out of service. Several futile attempts at invasion were followed by defeat or abortion, until the political officers were weeded out at the end of the year 1813, and Brown, Scott, Ripley, and others who had fought their way up were put in command. Then for the first time the men were drilled and brought into effective condition; and two successful battles in 1814—Chippewa and Lundy's Lane—threw some glory on the end of the war. So weak were the preparations even for defence that a British expedition in 1814 met no effective resistance when it landed and burned Washington. It was defeated, however, in an attempt to take Baltimore.

Chippewa and Lundy's Lane.

Washington burnt.

State of the Navy.

178. The American navy at the outbreak of the war numbered half a dozen frigates and about the same number of smaller vessels. This was but a puny adversary for the thousand sail of the British navy, which had captured or shut up in port all the other navies of Europe. But the small number of American vessels, with the superabundance of trained officers, gave them one great advantage: the training and discipline of the men, and the equipment of the vessels, had been brought to the very highest point. Captains who could command a vessel but for a short time, yielding her then to another officer who was to take his sea service in rotation, were all ambitious to make their mark during their term. "The art of handling and fighting the old broadside sailing frigate" had been carried in the little American navy to a point which unvarying success and a tendency to fleet-combats had now made far less common among British captains.¹

Naval successes.

179. The first year of the war saw five ship-duels, in all of which the American frigates either captured or sunk their adversaries. Four others followed in 1813, in two of which the British vessels came off victorious. The attention of the British Government had by that time been fully diverted to the North-American coast; its blockading fleets made it very difficult for the larger American vessels to get to sea; and there were but seven other ship-combats, in only one of which the American vessel was taken. Most of the work was done by three frigates, the "Constitution," the "Essex," and the "United States." There was fighting also on the Great Lakes between improvised fleets

of small vessels. Perry captured the British fleet on Lake Erie (1813) and Macdonough the British fleet on Lake Champlain (1814). The former victory led to the end of the war in the West. Harrison, the American commander in that section, shipped his army across the lake in Perry's fleet, and routed the British and Canadian army at the Thames.

180. The home dislike to the war had increased steadily with the evidence of incompetent management by the administration. The Federalists, who had always desired a navy, pointed to the naval successes as the best proof of the folly with which the war had been undertaken and managed. New England Federalists complained that the Federal Government utterly neglected the defence of their coast, and that Southern influence was far too strong in national affairs. They showed at every opportunity a disposition to adopt the furthest stretch of State sovereignty, as stated in the Kentucky resolutions; and every such development urged the national democracy unconsciously further on the road to nationality. When the New England States sent delegates to meet at Hartford and consider their grievances and the best remedies—a step perfectly proper on the Democratic theory of a "voluntary Union"—treason was suspected, and a readiness to suppress it by force was plainly shown. The recommendations of the convention came to nothing; but the attitude of the dominant party towards it is one of the symptoms of the manner in which the trials of actual war were steadily reconciling democracy and nationality. The object which Hamilton had sought by high tariffs and the development of national classes had been attained by more natural and healthy means.

181. In April 1814 the first abdication of Napoleon took place, and Great Britain was able to give more attention to her American antagonist. The main attack was to be made on Louisiana, the weakest and most distant portion of the Union. A fleet and army were sent thither, and, after much delay, landed below the city. The nearest settled country was Tennessee; and between it and New Orleans was a wilderness four hundred miles long. Andrew Jackson had become the most prominent citizen of Tennessee, and he was ordered to the defence of New Orleans. His popularity and energy brought riflemen down the river and put them into position. The British assault was marred by hopeless blunders, and the gallantry of the men only made their slaughter and repulse more complete (January 8, 1815). Peace had been made at Ghent fifteen days before the battle was fought, but the news of the battle and the peace reached Washington almost together, the former going far to make the latter tolerable.

182. Though the land war had gone almost uniformly against the United States, and the American naval successes had been just enough to irritate the English mind, and though the British negotiators had nothing to dread and everything to demand, the treaty was quite satisfactory to the United States. It is true that it said not a word about the questions of impressment, search, and neutral rights, the grounds of the war; Great Britain did not abandon her position on any of them. But everybody knew that circumstances had changed. The new naval power whose frigates alone in the past twenty years had shown their ability to fight English frigates on equal terms was not likely to be troubled in future with the question of impressment; and in fact, while not renouncing the right, the British Government no longer attempted to enforce it. The navy, it must be confessed, was the force which had at last given the United States a recognized and cordial acceptance in the family of nations; it had solved the problem of the reconciliation of democracy and nationality. From this time the dominant party shows an

¹ The naval officers who came most prominently to notice in the war were Hull and Lawrence (see p. 789) and the following:—STEPHEN DECATUR was born at Sinnepuxent, Md., Jan. 5, 1779, and died at Washington (shot in a duel), March 22, 1820. He distinguished himself in the first Algerine war, 1803-4, by his capture of the British frigate "Macedonian," while in command of the "United States," and in the brief war which brought about the final submission of the Algerines in 1815.—THOMAS MACDONOUGH was born in Newcastle county, Del., Dec. 23, 1783, and died at sea, Nov. 16, 1825. He was commodore of the American fleet on Lake Champlain, in its victory over the British fleet.—OLIVER HAZARD PERRY was born at South Kingston, R.I., Aug. 23, 1785, and died on the island of Trinidad, Aug. 23, 1819. His great achievement was his victory over the British fleet, 1813, laconically announced in the despatch: "We have met the enemy, and they are ours."—DAVID PORTER was born at Boston, Mass., Feb. 1, 1780. After service in a merchantman, he entered the navy in 1798, served in the Algerine war and elsewhere, and in 1812 was in command of the "Essex." His most brilliant service was his cruise in the Pacific in 1813-14, in which he swept that ocean of British whalers, and was finally captured in the neutral harbour of Valparaiso by two British vessels, after the most desperate naval combat of the war. He resigned in 1826, after a difficulty with the navy department, and took command of the Mexican navy. He died near Constantinople, March 28, 1843, while serving as minister to Turkey. See D. D. Porter's *Memoir of David Porter* (1876), and Irving's *Spanish Papers*, vol. ii.—JOHN RODGERS was born in Harford county, Md., in 1771. He entered the navy in 1798 as a lieutenant, rose to a captaincy, commanded the Mediterranean fleet in 1805, and the frigate "President" during the encounter with the "Little Belt" in 1811. He was in command of the fleet at New York in 1812, and hurried it to sea, lest his Government should forbid it to leave port. He commanded the fleet in another cruise the same year, but only individual captures were made. He died at Philadelphia, Aug. 1, 1838.

increasing disposition to exalt and maintain the national element of the American system.

Extinction of the Federal party. 183. The remainder of this period is one of the barrenest in American history. The opposition of the Federal party to the war completed the measure of its unpopularity, and it had only a perfunctory existence for a few years longer. There was but one real party, and the political struggles within it tended to take the shape of purely personal politics. Scandal, intrigue, and personal criticism became the most marked characteristics of American politics until the dominant party broke at the end of the period, and real party conflict was renewed. But the seeds of the final disruption are visible from the peace of 1814. The old-fashioned Republicans looked with intense suspicion on the new form of Republicanism generated by the war, a type which instinctively bent its energies toward the further development of national power. Clay was the natural leader of the new democracy; but John Quincy Adams and others of Federalist antecedents or leanings took to the new doctrines kindly; and even Calhoun, Crawford (p. 788), and others of the Southern interest were at first strongly inclined to support them. One of the first effects was the revival of protection and of a national bank.

Bank of the United States. 184. The charter of the national bank (§ 146) had expired in 1811, and the dominant party had refused to recharter it. The attempt to carry on the war by loans resulted in almost a bankruptcy and in a complete inability to act efficiently. As soon as peace gave time for consideration, a second bank was chartered for twenty years, with a capital of \$35,000,000, four-fifths of which might be in Government stock. It was to have the custody of the Government revenues, but the secretary of the treasury could divert the revenues to other custodians, giving his reasons for such action to Congress. This clause, meant to cover cases in which the Bank of the United States had no branch at a place where money was needed, was afterwards put to use for a very different purpose (§ 204).

Protection. 185. Protection was advocated again on national grounds, but not quite on those which had moved Hamilton (§ 146). The additional receipts were now to be expended for fortifications and other national defences, and for national roads and canals, the latter to be considered solely as military measures, with an incidental benefit to the people. Business distress among the people gave additional force to the proposal. The war and blockade had been an active form of protection, under which American manufactures had sprung up in great abundance. As soon as peace was made English manufacturers poured their products into the United States, and drove their American rivals out of business or reduced them to desperate straits. Their cries to Congress for relief had a double effect. They gave the spur to the nationalizing advocates of protection, and, as most of the manufacturers were in New England or New York, they developed in the citadel of Federalism a class which looked for help to a Republican Congress, and was therefore bound to oppose the Federal party. This was the main force which brought New England into the Republican fold before 1825. An increase in the number of spindles from 80,000 in 1811 to 500,000 in 1815, and in cotton consumption from 500 bales in 1800 to 90,000 in 1815, the rise of manufacturing towns, and the rapid development of the mechanical tendencies of a people who had been hitherto almost exclusively agricultural, were influences which were to be reckoned with in the politics of a democratic country.

Tariff of 1816. 186. The tariff of 1816 imposed a duty of about 25 per cent. on imports of cotton and woollen goods, and specific duties on iron imports. The *ad valorem* duties carried most of the manufacturers through the financial crisis of

1818-19, but the iron duties were less satisfactory. In English manufacture the substitution of coke for charcoal in iron production led to continual decrease in price. As the price went down the specific duties were continually increasing the absolute amount of protection. Thus spared the necessity for improvements in production, the American manufacturers felt English competition more keenly as the years went by, and called for more protection.

187. Monroe succeeded Madison as president in 1817, "Era of and, re-elected with hardly any opposition in 1820, he served until 1825. So complete was the supremacy of the good feeling." Republican party that this is often called "the era of good feeling." It came to an end when a successor to Monroe was to be elected; the two sections of the dominant party then had their first opportunity for open struggle. During Monroe's two terms of office the nationalizing party developed the policy on which it proposed to manage national affairs. This was largely the product of the continually swelling western movement of population. The influence of the steamboat was felt more and more every year, and the want of a similar improvement in land transport was correspondingly evident. The attention drawn to western New York by the war had filled that part of the State with a new population. The Southern Indians had been completely overthrown by Jackson during the war of 1812, and forced to cede their lands; all the territory west of Georgia was thus opened up to settlement. The admission of the new States of Indiana (1816), Mississippi (1817), Illinois (1818), Alabama (1819), Maine (1820), and Missouri (1821)—all but Maine the product and evidence of Western growth—were the immediate results of the development consequent upon the war. All the territory east of the Mississippi, except the northern part of the north-west territory, was now formed into self-governing States; the State system had already crossed the Mississippi; and all that was needed for further development was the locomotive engine. The four millions of 1790 had grown into thirteen millions in 1830; and there was a steady increase of one-third in each decade.

188. The urgent demand of Western settlers for some road to a market led to a variety of schemes to facilitate intercourse between the East and the West,—the most successful being that completed in New York in 1825, the Erie Canal. The Hudson river forms the great Erie natural breach in the barrier range which runs parallel to the Atlantic coast. When the traveller has passed up the Hudson through that range he sees before him a vast champaign country extending westward to the Great Lakes, and perfectly adapted by nature for a canal. Such a canal, to turn Western traffic into the lake rivers and through the lakes, the canal, and the Hudson to New York city, was begun by the State through the influence of De Witt Clinton, was derisively called "Clinton's big ditch" until its completion, and laid the foundations for the great commercial prosperity of New York State and city. Long before it was finished the evident certainty of its success had seduced other States into far less successful enterprises of the kind and had established as a nationalizing policy the combination of high tariffs and expenditures for internal improvements which was long known as the "American system." The tariffs of duties on imports were to be carried as high as revenue results would approve; within this limit the duties were to be defined for purposes of protection; and the superabundant revenues were to be expended for the improvement of roads, rivers, and harbours, and for every enterprise which would tend to aid the people in their efforts to subdue the continent. Protection was now to be for national benefit, not for the benefit of classes. Western farmers were to have manufacturing towns at their doors, as markets for the surplus which had hitherto

been rotting on their farms; competition among manufacturers was to keep down prices; migration to all the new advantages of the West was to be made easy at national expense; and Henry Clay's eloquence was to commend the whole policy to the people. The old Democracy, particularly in the South, insisted that the whole scheme really had its basis in benefits to classes, that its communistic features were not such as the constitution meant to cover by its grant of power to Congress to levy taxation for the general welfare, and that any such legislation would be unconstitutional. The dissatisfaction in the South rose higher when the tariffs were increased in 1824 and 1828. The proportion of customs revenue to dutiable imports rose to 37 per cent. in 1825 and to 44 per cent. in 1829; and the ratio to aggregate imports to 33 per cent. in 1825 and 37 per cent. in 1829. As yet, however, the Southern dissatisfaction showed itself only in resolutions of State legislatures.

Tariffs of 1824 and 1828.

189. In the sudden development of the new nation circumstances had conspired to give social forces an abnormally materialistic cast, and this had strongly influenced the expression of the national life. Its literature and its art had amounted to little, for the American people were still engaged in the fiercest of warfare against natural difficulties, which absorbed all their energies.

190. In international relations the action of the Government was strong, quiet, and self-respecting. Its first weighty action took place in 1823. It had become pretty evident that the Holy Alliance, in addition to its interventions in Europe to suppress popular risings, meant to aid Spain in bringing her revolted South-American colonies to obedience. Great Britain had been drifting steadily away from the Alliance, and Canning, the new secretary, determined to call in the weight of the trans-Atlantic power as a check upon it. A hint to the American minister was followed by a few pregnant passages in President Monroe's annual message in December. Stating the friendly relations of the United States with the new South-American republics, he went on to say, "We could not view an interposition for oppressing them (the South-American states), or controlling in any other manner their destiny by any European power, in any other light than as a manifestation of an unfriendly disposition towards the United States." If both the United States and Great Britain were to take this ground the fate of a fleet sent by the Alliance across the Atlantic was not in much doubt, and the project was at once given up. The "Monroe doctrine," however, has remained the rule of foreign intercourse for all American parties. Added to the already established refusal of the United States to become entangled in any European wars or alliances, it has separated the two continents, to their common advantage.

The Monroe doctrine.

The colonial clause.

191. It was supposed at the time that Spain might transfer her colonial claims to some stronger power; and Mr Monroe therefore went on to say that "the American continents should no longer be subjects for any new European colonial settlement." The meaning of this was well understood at the time; and, when its condition failed, the statement lost its force. It has been supposed that it bound the United States to resist any further establishment of European colonies in the Americas. Such a rôle of universal arbiter has always been repudiated by the United States, though its sympathies, more or less active, must always go with any American republic which falls into collision with any such colonizing scheme.

The north-west boundary.

192. By a treaty with Russia (1825) that power gave up all claims on the Pacific coast south of the present limits of Alaska. The northern boundary of the United States had been settled by the treaty of 1783; and, after the acquisition of Louisiana, a convention with Great

Britain settled the boundary on the line of 49° N. lat. as far west as the Rocky Mountains (1818). West of these mountains the so-called Oregon country (§ 168). ^{on whose} limits the two powers could not agree, was to be held in common possession for ten years. This common possession was prolonged by another convention (1827) indefinitely, with the privilege to either power to terminate it on giving twelve months' notice. This arrangement lasted until 1846 (§ 224).

193. Monroe's terms of office came to an end in 1825. He had originally been an extreme Democrat, who could hardly speak of Washington with patience; he had slowly changed into a very moderate Republican, whose tendencies were eagerly claimed by the few remaining Federalists as identical with their own. The nationalizing faction of the dominant party had scored almost all the successes of the administration, and the divergence between it and the opposing faction was steadily becoming more apparent. All the candidates for the presidency in 1824—Andrew Jackson, a private citizen of Tennessee; William H. Crawford, Monroe's secretary of the treasury; John Quincy Adams, his secretary of state; and Henry Clay, the speaker of the house of representatives—claimed to be Republicans alike; but the personal nature of the struggle was shown by the tendency of their supporters to call themselves "Adams men" or "Jackson men," rather than by any real party title. Calhoun was supported by all parties for the vice-presidency, and was elected without difficulty. The choice of a president was more doubtful.

194. None of the four candidates had anything like a Party organization behind him. Adams and Clay represented the nationalizing element, as Crawford and Jackson did not; but there the likeness among them stopped. The strongest forces behind Adams were the new manufacturing and commercial interests of the East; behind Clay were the desires of the West for internal improvements at public expense as a set-off to the benefits which the seaboard States had already received from the Government; and the two elements were soon to be united into the National Republican or Whig party. Crawford was the representative of the old Democratic party, with all its Southern influence and leanings. Jackson was the personification of the new democracy,—not very cultured, perhaps, but honest, and hating every shade of class control instinctively. As he became better known the whole force of the new drift of things turned in his direction; "hurrah for Jackson" undoubtedly often represented tendencies which the speaker would have found it hard to express otherwise. Crawford was taken out of the race, just after this election, by physical failure, and Adams by the revival of ancient quarrels with the Federalists of New England; and the future was to be with Clay or with Jackson. But in 1824 the question of success among the four was not an easy one to decide. The electors gave no one a majority; and the house of representatives gave the presidency to Adams (§§ 119, 120).

195. Adams's election in 1824 was due to the fact that Clay's friends in the house—unable to vote for him, as he was the lowest in the electoral vote, and only three names were open to choice in the house—very naturally gave their votes to Adams. As Adams appointed Clay to the leading position in his cabinet, the defeated party at once raised the cry of "bargain and intrigue," one of the most effective in a democracy, and it was kept up throughout Adams's four years of office. Jackson had received the largest number of electoral votes, though not a majority; and the hazy notion that he had been injured because of his devotion to the people increased his popularity. Though demagogues made use of it for selfish purposes, this feeling was an honest one, and Adams had nothing to oppose to it.

The Adams administration.

He tried vigorously to uphold the "American system," and succeeded in passing the tariff of 1828; he tried to maintain the influence of the United States on both the American continents; but he remained as unpopular as his rival grew popular. In 1828 Adams was easily displaced by Jackson. Calhoun was re-elected vice-president.

Election
of 1828.

Democ-
racy
and
nation-
ality.

196. Jackson's inauguration in 1829 closes this period, as it ends the time during which a disruption of the Union by the peaceable withdrawal of any State was even possible. The party which had made State sovereignty its bulwark in 1798 was now in control of the Government again; but Jackson's proclamation in his first term, in which he warned South Carolina that "disunion by armed force is treason," and that blood must flow if the laws were resisted, speaks a very different tone from the speculations of Jefferson on possible future divisions of the United States. And even the sudden attempt of South Carolina to exercise independent action (§ 206), which would have been looked upon as almost a right forty years before, shows that some interest dependent upon State sovereignty had taken alarm at the evident drift of events, and was anxious to lodge a claim to the right before it should slip from its fingers for ever. Nullification was but the first skirmish between the two hostile forces of slavery and democracy.

Slavery.

197. When the vast territory of Louisiana was acquired in 1803 the new owner found slavery already established there by custom recognized by French and Spanish law. Congress tacitly ratified existing law by taking no action; slavery continued legal, and spread further through the territory; and the State of Louisiana entered as a slave State in 1812. The next State to be carved out of the territory was Missouri, admitted in 1821. A Territory, on applying for admission as a State, brings a constitution for inspection by Congress; and, when it was found that the new State of Missouri proposed to recognize and continue slavery, a vigorous opposition spread through the North and West, and carried most of the senators and representatives from those sections with it. In the house of representatives these two sections had a greatly superior number of members; but, as the number of Northern and Southern States had been kept about equal, the compact Southern vote, with one or two Northern allies, generally retained control of the senate. Admitted by the senate and rejected by the house, Missouri's application hung suspended for several years, until it was successful by the admission of Maine, a balancing Northern State, and by the following arrangement, known as the Missouri compromise of 1820:—Missouri was to enter as a slave State; slavery was for ever prohibited throughout the rest of the Louisiana purchase north of lat. 36° 30', the main southern boundary of Missouri; and, though nothing was said of the territory south of the compromise line, it was understood that any State formed out of it was to be a slave State, if it so wished (§ 249). Arkansas entered under this provision in 1836.

The
Missouri
compro-
mise.

Sectional
diver-
gence.

198. The question of slavery was thus set at rest for the present, though a few agitators were roused to more zealous opposition to the essence of slavery itself. In the next decade these agitators succeeded only in the conversion of a few recruits, but these recruits were the ones who took up the work at the opening of the next period and never gave it up until slavery was ended. It is plain now, however, that North and South had already drifted so far apart as to form two sections, and that, as things stood, their drift for the future could only be further apart, in spite of the feeble tie furnished by the Missouri compromise. It became evident, during the next forty years, that the wants and desires of these two sections were so divergent that it was impossible for one Government to make satis-

factory laws for both. The moving cause was not removed in 1820; one of its effects was got out of the way for the time, but others were soon to take its place.

199. The vast flood of human beings which had been The pouring westward for years had now pretty well occupied settled the territory east of the Mississippi, while, on the west side area. of that stream, it still showed a disposition to hold to the river valleys. The settled area had increased from 240,000 square miles in 1790 to 633,000 square miles in 1830, with an average of 20.3 persons to the square mile. There was still a great deal of Indian territory in the Southern States of Georgia, Alabama, and Mississippi, and in Florida, for the southern Indians were among the finest of their race; they had become semi-civilized, and were formidable antagonists to the encroaching white race. The States interested had begun preparations for their forcible removal, in public defiance of the attempts of the Federal Government to protect the Indians (1827); but the removal was not completed until 1835. In the North, Wisconsin and Michigan, with the northern halves of Illinois and Indiana, were still very thinly settled, but everything indicated early increase of population. The first lake steamboat, the "Walk-in-the-Water," had appeared at De- The steam- troit in 1818, and the opening of the Erie Canal added to boat. the number of such vessels. Lake Erie had seven in 1826; and in 1830, while the only important lake town, Detroit, was hardly yet more than a frontier fort, a daily line of steamers was running to it from Buffalo, carrying the increasing stream of emigrants to the Western territory.

200. The land system of the United States had much The to do with the early development of the West. From the land system. first settlement, the universally recognized rule had been that of absolute individual property in land, with its corollary of unrestricted competitive or "rack" rents; and this rule was accepted fully in the national land system, whose basis was reported by Jefferson, as chairman of a committee of the Confederation Congress (1785). The public lands were to be divided into hundreds of ten miles square, each containing one hundred mile-square plots. The hundred was called a "township," and was afterward reduced to six miles square, of thirty-six mile-square plots of 640 acres each. From time to time principal meridians and east and west base lines have been run, and townships have been determined by their relations to these lines. The sections (plots) have been subdivided, but the transfer describes each parcel from the survey map, as in the case of "the south-west quarter of section 20, township 30, north, range 1 east of the third principal meridian." The price fixed in 1790 as a minimum was \$2 per acre; it has tended to decrease, and no effort has ever been made to gain a revenue from it. When the nation acquired its Western territory it secured its title to the soil, and always made it a fundamental condition of the admission of a new State that it should not tax United States lands. To compensate the new States for the freedom of unsold public lands from taxation, one township in each thirty-six was reserved to them for educational purposes; and the excellent public school systems of the Western States have been founded on this provision. The cost of obtaining a quarter section (160 acres), under the still later homestead system of granting lands to actual settlers, has come to be only about \$26; the interest on this, at 6 per cent., represents an annual rent of one cent per acre,—making this, says F. A. Walker, as nearly as possible the "no-rent land" of the economists.

201. The bulk of the early westward migration was of Immigra- home production; the great immigration from Europe did tion. not begin until about 1847 (§ 236). The West as well as the East thus had its institutions fixed before being called upon to absorb an enormous foreign element.

VIII. INDUSTRIAL DEVELOPMENT AND SECTIONAL
DIVERGENCE: 1829-50.

New political methods. 202. The eight years after 1829 have been called "the reign of Andrew Jackson"; his popularity, his long struggle for the presidency, and his feeling of his official ownership of the subordinate offices gave to his administration at least an appearance of Caesarism. But it was a strictly constitutional Caesarism; the restraints of written law were never violated, though the methods adopted within the law were new to national politics. Since about 1800 State politics in New York and Pennsylvania had been noted for the systematic use of the offices and for the merciless manner in which the office-holder was compelled to work for the party which kept him in place. The presence of New York and Pennsylvania politicians in Jackson's cabinet taught him to use the same system. Removals, except for cause, had been almost unknown before; but under Jackson men were removed almost exclusively for the purpose of installing some more serviceable party tool; and a clean sweep was made in the civil service. Other parties adopted the system, and it has remained the rule at a change of administration until comparatively recent years (§ 323).

The new organization of parties. 203. The system brought with it a semi-military reorganization of parties. Hitherto nominations for the more important offices had been made mainly by legislative caucuses; candidates for president and vice-president were nominated by caucuses of Congressmen, and candidates for the higher State offices by caucuses of the State legislatures. Late in the preceding period "conventions" of delegates from the members of the party in the State occur in New York and Pennsylvania; and in 1831-32 this became the rule for presidential nominations. It rapidly developed into systematic State, county, and city "conventions"; and the result was the appearance of that complete political machinery, the American political party, with its local organizations, and its delegates to county, State, and national conventions. The Democratic machinery was the first to appear, in Jackson's second term (1833-37). Its workers were paid in offices, or hopes of office, so that it was said to be built on the "cohesive power of public plunder"; but its success was immediate and brilliant. The opposing party, the Whig party, had no chance of victory in 1836; and its complete overthrow drove its leaders into the organization of a similar machinery of their own, which scored its first success in 1840. Since that time these strange bodies, unknown to the law, have governed the country by turns; and their enormous growth has steadily made the organization of a third piece of such machinery more difficult or hopeless.

Bank of the United States. 204. The Bank of the United States had hardly been heard of in politics until the new Democratic organization came into hostile contact with it. A semi-official demand upon it for a political appointment was met by a refusal; and the party managers called Jackson's attention to an institution which he could not but dislike the more he considered it. His first message spoke of it in unfriendly terms, and every succeeding message brought a more open attack. The old party of Adams and Clay had by this time taken the name of Whigs, probably from the notion that they were struggling against "the reign of Andrew Jackson," and they adopted the cause of the bank with eagerness. The bank charter did not expire until 1836, but in 1832 Clay brought up a bill for a new charter. It was passed and vetoed (§ 113); and the Whigs went into the presidential election of that year on the veto. They were beaten; Jackson was re-elected; and the bank party could never again get a majority in the house of representatives for the charter. The insistence of the president on the point that the charter was a "monopoly" bore

weight with the people. But the president could not obtain a majority in the senate. He determined to take a step which would give him an initiative, and which his opponents could not induce both houses to unite in over-riding or punishing. Taking advantage of the provision that the secretary of the treasury might order the public funds to be deposited elsewhere than in the bank or its branches (§ 184), he directed the secretary to deposit all the public funds elsewhere. Thus deprived of its great source of dividends, the bank fell into difficulties, became a State bank after 1836, and then went into bankruptcy.

205. All the political conflicts of Jackson's terms of office were close and bitter. Loose in his ideas before 1829, Jackson shows a steady tendency to adopt the strictest construction of the powers of the Federal Government, except in such official perquisites as the offices. He grew into strong opposition to all traces of the "American system," and vetoed bills for internal improvements unsparringly; and his feeling of dislike to all forms of protection is as evident, though he took more care not to make it too public. There are many reasons for believing that his drift was the work of a strong school of leaders—Van Buren, Benton (p. 788), Livingston, Taney (p. 790), Woodbury (p. 790), Cass, Marcy (p. 789), and others—who developed the policy of the party, and controlled it until the great changes of parties about 1850 took their power from them. At all events, some persistent influence made the Democratic party of 1830-50 the most consistent and successful party which had thus far appeared in the United States.

206. Calhoun and Jackson were of the same stock—Calhoun Scottish-Irish,—much alike in appearance and characteristics, the former representing the trained and educated logic of the race, the latter its instincts and passions. Jackson was led to break off his friendly relations with Calhoun in 1830, and he had been led to do so more easily because of the appearance of the doctrine of nullification, which was generally attributed, correctly enough, to the authorship of Calhoun. Asserting, as the Republican party of 1798 had done, the sovereign powers of each State, Calhoun held that, as a means of avoiding secession and violent struggle upon every occasion of the passage of an Act of Congress which should seem unconstitutional to any State, the State might properly suspend or "nullify" the operation of the law within its jurisdiction, in order to protect its citizens against oppression. Webster, of Massachusetts, and Hayne, of South Carolina, debated the question in the senate in 1830, and the supporters of each claimed a virtual victory for their leader. The passage of the Tariff Act of 1832, which organized and systematized the protective system, forced the Calhoun party into action. A State convention in South Carolina declared the Tariff Act null and not law or binding on the people of the State, and made ready to enforce the declaration. Nullification.

207. But the time was past when the power of a single State could withdraw it from the Union. The president issued a proclamation, warning the people of South Carolina against any attempt to carry out the ordinance of nullification; he ordered a naval force to take possession of Charleston harbour to collect the duties under the Act; he called upon Congress for additional executive powers, and Congress passed what nullifiers called the "bloody bill," putting the land and naval forces at the disposal of the president for the collection of duties against "unlawful combinations;" and he is said to have announced, privately and profanely, his intention of making Calhoun the first victim of any open conflict. Affairs looked so threatening that an unofficial meeting of "leading nullifiers" agreed to suspend the operation of the ordinance until Congress should adjourn; whence it derived the right to suspend has never been stated.

208. The president had already asked Congress to reduce the duties; and many Democratic members of Congress, who had yielded to the popular clamour for Protection, were very glad to use "the crisis" as an excuse for now voting against it. A compromise Tariff Act, scaling down all duties over 20 per cent. by one-tenth of the surplus each year, so as to bring duties to a uniform rate of 20 per cent. in 1843, was introduced by Clay and became law. Calhoun and his followers claimed this as all that the nullification ordinance had aimed at; and the ordinance was formally repealed. But nullification had received its death-blow; even those Southern leaders who maintained the right of secession refused to recognize the right of a State to remain in the Union while nullifying its laws; and, when protection was reintroduced by the tariff of 1842, nullification was hardly thought of.

209. All the internal conditions of the United States were completely altered by the introduction of railways. For twenty years past the Americans had been pushing in every direction which offered a hope of the means of reconciling vast territory with enormous population. Stephenson's invention of the locomotive came just in time, and Jackson's two terms of office marked the outburst of modern American life. English engines were brought over in 1829, and served as models for a year or two; and then the lighter forms of locomotives, better suited to American conditions, were introduced. The miles of railroad were 23 in 1830, 1098 in 1835, nearly 2000 in 1840, and thereafter they about doubled every five years until 1860.

210. A railway map of 1840 shows a fragmentary system, designed mainly to fill the gaps left by the means of communication in use in 1830. One or two short lines run back into the country from Savannah and Charleston; another runs north along the coast from Wilmington to Baltimore; several lines connect New York with Washington and other points; and short lines elsewhere mark the openings which needed to be filled at once—a number in New England and the middle States, three in Ohio and Michigan, and three in Louisiana. Year after year new inventions came in to increase and aid this development. The anthracite coal of the middle States had been known since 1790 (§ 19), but no means had been devised to put the refractory agent to work. It was now successfully applied to railroads (1836), and to the manufacture of iron (1837). Hitherto wood had been the best fuel for iron-making; now the States which relied on wood were driven out of competition, and production was restricted to the States in which nature had placed coal alongside of iron. Steam navigation across the Atlantic was established in 1838. The telegraph came next, Morse's line being erected in 1844. The spread of the railway system brought with it, as a natural development, the rise of the American system of express companies, whose first phases of individual enterprise appeared in 1839. No similar period in American history is so extraordinary for material development as the decade 1830-40. At its beginning the country was an overgrown type of colonial life; at its end American life had been shifted to entirely new lines, which it has since followed. Modern American history had burst in with the explosiveness of an Arctic summer.

211. If the steamboat had aided Western development, the railway made it a freshet. Cities and States grew as if the oxygen of their surroundings had been suddenly increased. The steamboat influenced the railway, and the railway gave the steamboat new powers. Vacant places in the States east of the Mississippi were filling up; the long lines of emigrant waggons gave way to the new and better methods of transport; and new grades of land were made accessible. Chicago was but a frontier fort in 1832; within a half-dozen years it was a flourishing

town, with eight steamers connecting it with Buffalo, and dawning ideas of its future development of railway connexions. The maps change from decade to decade, as map-makers hasten to insert new cities which have sprung up. Two new States, Arkansas and Michigan, were admitted (1836 and 1837). The population of Ohio leaps from 900,000 to 1,500,000, that of Michigan from 30,000 to 212,000, and that of the country from 13,000,000 to 17,000,000, between 1830 and 1840.

212. With the change of material surroundings and possibilities came a steady amelioration of social conditions and a development of social ideals. Such features of the past as imprisonment for debt and the cruel indifference of old methods of dealing with crime began to disappear; the time was past when a State could use an abandoned copper-mine as its State prison. The domestic use of gas and anthracite coal, the introduction of expensive aqueducts for pure water, and the changing life of the people forced changes in the interior and exterior of American dwellings. Wood was still the common building material; imitations of Greek architecture still retained their vogue; but the interiors were models of comfort in comparison with the houses even of 1810. In the "new" regions this was not yet the case, and here social restraints were still so few that society seemed to be reduced almost to its primitive elements. Western steamers reeked with gambling, swindling, duelling, and every variety of vice. Public law was almost suspended in some regions; and organized associations of counterfeiters and horse-thieves terrorized whole sections of country. But this state of affairs was altogether temporary, as well as limited in its area; the older and more densely settled States had been well prepared for the change and had never lost command of the social forces, and the process of settling down went on, even in the newer States, with far more rapidity than could reasonably have been expected. Those who took part in the movements of population in 1830-40 had been trained under the rigid forms of the previous American life; and these soon re-asserted themselves. The rebound was over before 1847, and the Western States were then as well prepared to receive and digest the great immigration which followed as the older States would have been in 1830.

213. A distinct American literature dates from this period. Most of the publications in the United States were still cheap reprints of foreign works; but native productions no longer followed foreign models with servility. Between 1830 and 1840 Whittier, Longfellow, Holmes, Poe, Hawthorne, Emerson, Bancroft, and Prescott joined the advance-guard of American writers—Bryant, Dana, Halleck, Drake, Irving, and Cooper; and even those writers who had already made their place in literature showed the influence of new conditions by their growing tendency to look less to foreign models and methods than before 1830. Popular education was improved. The new States had from the first endeavoured to secure the best possible system of common schools. The attempt came naturally from the political instincts of the class from which the migration came; but the system which resulted was to be of incalculable service during the years to come. Their absolute democracy and their universal use of the English language have made the common schools most successful machines for converting the raw material of immigration into American citizens. This supreme benefit is the basis of the system and the reason for its existence and development, but its incidental benefit of educating the people has been beyond calculation. It was an odd symptom of the general change that American newspapers took a new form during these ten years. The old "blanket-sheet" newspaper, cumbrous to handle and slow in all its ways, met its first rival in the type of newspaper which

appeared first in New York city, in the *Sun*, the *Herald*, and the *Tribune* (1833, 1835, and 1841). Swift and energetic in gathering news, and fearless, sometimes reckless, in stating it, they brought into American life, with very much that is evil, a great preponderance of good.

Land
sales.

214. The chaos into which a part of American society had been thrown had a marked effect on the financial institutions of the country, which went to pieces before it for a time. It had not been meant to make the public lands of the United States a source of revenue so much as a source of development. The sales had touched their high-water mark during the speculative year 1819, when receipts from them had amounted to \$3,274,000; in other years they seldom went above \$2,000,000. When the railroad set the stream of migration moving faster than ever, and cities began to grow like mushrooms, it was natural that speculation in land should feel the effects. Sales rose to \$3,200,000 in 1831, to \$4,000,000 in 1833, to \$5,000,000 in 1834, to \$15,000,000 in 1835, and to \$25,000,000 in 1836. In 1835 the president announced to Congress that the public debt was extinguished, and that some way of dealing with the surplus should be found. Calhoun's proposal, that after the year 1836 all revenue above \$5,000,000 should be divided among the States as a loan, was adopted, though only one such loan was made. The States had already taken a hand in the general speculation by beginning works of public improvement. Foreign, particularly English, capital was abundant; and States which had been accustomed to think a dozen times over a tax of a hundred thousand dollars now began to negotiate loans of millions of dollars and to appropriate the proceeds to the digging of canals and the construction of railroads. Their enterprises were badly conceived and badly managed, and only added to the confusion when the crash came. If the Federal Government and the States felt that they were rich, the imaginations of individuals ran riot. Every one wanted to buy; prices rose, and every one was growing rich on paper. The assessed value of real estate in New York city in 1832 was \$104,000,000; in 1836 it had grown to \$253,000,000. In Mobile the assessed value rose from \$1,000,000 to \$27,000,000. Fictitious values were the rule everywhere.

Speculation.

215. When Jackson (1833) ordered the Government revenues to be deposited elsewhere than in the Bank of the United States (§ 204), there was no Government agent to receive them. The secretary of the treasury selected banks at various points in which the revenue should be deposited by the collecting officers; but these banks were organized under charters from their States, as were all banks except that of the United States. The theory of the dominant party denied the constitutional power of Congress to charter a bank, and the States had not yet learned how to deal with such institutions. Their grants of bank charters had been based on ignorance, intrigue, favouritism, or corruption, and the banks were utterly unregulated. The democratic feeling was that the privilege of forming banking corporations should be open to all citizens, and it soon became so. Moreover it was not until after the crash that New York began the system of compelling such deposits as would really secure circulation, which was long afterward further developed into the present national bank system. In most of the States banks could be freely organized with or without tangible capital, and their notes could be sent to the West for the purchase of Government lands, which needed to be held but a month or two to gain a handsome profit. "Wild-cat banks" sprang up all over the country; and the "pet banks," as these chosen for the deposit of Government revenues were called by their rivals, went into speculation as eagerly as the banks which hardly pretended to have capital.

Corporations.

216. The Democratic theory denied the power of Congress to make anything but gold or silver legal tender. There have been "paper-money heresies" in the party; but there were none such among the new school of Democratic leaders which came in in 1829; they were "hard-money men." In 1836 Jackson's secretary of the treasury ordered land agents to take nothing in payment for lands except gold or silver. In the following spring the full effects of the order became evident; they fell on the administration of Van Buren, Jackson's successor. Van Buren had been Jackson's secretary of state, the representative man of the new Democratic school, and, in the opinion of the opposition, the evil genius of the Jackson administration; and it seemed to the Whigs poetic justice that he should bear the weight of his predecessor's errors. The "specie circular" turned the tide of paper back to the East, and, when it was presented for payment most of the banks suspended specie payment with hardly a struggle. There was no longer a thought of buying; every one wanted to sell; and prices ran down with a rapidity even more startling than that with which they had risen. Failures, to an extent and on a scale unprecedented in the United States, made up the "panic of 1837." Many of the States had left their bonds in the hands of their agents, and, on the failure of the latter, found that the bonds had been hypothecated or disposed of, so that the States got no return from them except a debt which was to them enormous. Saddled suddenly with such a burden, and unable even to pay interest, many of the States "repudiated" their obligations; and repudiation was made successful by the fact that a State cannot be sued except by its own consent (§ 65). Even the Federal Government felt the strain, for its revenues were locked up in suspended banks. A little more than a year after Congress had authorized the distribution of its surplus revenues among the States Van Buren was forced to call it into special session to provide some relief for the Government itself.

217. Van Buren held manfully to the strictest construction of the powers of the Federal Government. He insisted that the panic would best right itself without Government interference, and, after a four years' struggle, he succeeded in making the "sub-treasury scheme" law (1840). It cut off all connexion of the Government with banks, putting collecting and disbursing officers under bonds to hold money safely and to transfer it under orders from the treasury, and restricting payments to or by the United States to gold and silver. Its passage had been preceded by another commercial crisis (1839), more limited in its field, but more discouraging to the people. It is true that Jackson, in dealing with the finances, had "simply smashed things," leaving his successor to repair damages; but it is far from certain that this was not the best way available at the time. The wisest scheme of financial reform would have had small chance of success with the land-jobbers in Congress; and Van Buren's firmness found the way out of the chaos.

218. Van Buren's firmness was unpopular; and the Whig party now adopted methods which were popular, if somewhat demagogical. It nominated Harrison in 1840; it contrasted his homely frontier virtues with Van Buren's "ostentatious indifference to the misfortunes of the people" and with the supposed luxury of his life in the White House; and, after the first of the modern "campaigns" of mass meetings and processions, Harrison was elected. He died soon after his inauguration (1841), and the vice-president, Tyler, became president. Tyler was of the extreme Calhoun school, which had shown some disposition to grant to Van Buren a support which it had refused to Jackson; and the Whigs had nominated Tyler to retain his faction with them. Now he was the nominal leader of

the party, while his politics were opposite to theirs, and the real leader of the party, Clay, was ready to force a quarrel upon him. The quarrel took place; the Whig majority in Congress was not large enough to pass any measures over Tyler's veto; and the first two years of his administration were passed in barren conflict with his party. The "sub-treasury" law was repealed (1841); the tariff of 1842 introduced a modified protection; and there the Whigs were forced to stop. Their dissensions made Democratic success comparatively easy, and Tyler had the support of a Democratic house behind him during the last two years of his term.

219. The success of the Democratic machinery, and the reflex of its temporary check in 1840, with the influences brought to bear on it by the returning Calhoun faction, were such as to take the control of the party out of the hands of the leaders who had formed it. They had had high regard for political principle, even though they were willing to use doubtful methods for its propagation; these methods had now brought out new men, who looked mainly to success, and to close connexion with the controlling political element of the South as the easiest means of attaining success. When the Democratic convention of 1844 met it was expected to renominate Van Buren. A majority of the delegates had been sent there for that purpose, but many of them would have been glad to be prevented from doing so. They allowed a resolution to be passed making a two-thirds vote necessary for nomination; Van Buren was unable to command so many votes; and, when his name was withdrawn, Polk was nominated. The Whigs nominated Clay.

Abolitionist
movement.

220. The beginning of the abolitionist movement in the United States, the establishment of the *Liberator* (1831) and of the American Anti-Slavery Society (1833), and the subsequent divisions in it, are given elsewhere (see *Ency. Brit.*, vol. x. pp. 86, 87). Up to that time "abolition" had meant *gradual* abolition; it was a wish rather than a purpose. Garrison called for *immediate* abolition. The basis of the American system was in the reserved rights of the States, and slavery rested on their will, which was not likely to be changed. But the cry was kept up. The mission of the abolitionists was to force the people to think of the question; and, in spite of riots, assaults, and persecution of every kind, they fulfilled it manfully. It was inevitable that, as the Northern people were brought unwillingly to think of the question, they should look with new eyes on many of its phases; while in the South many who might dislike slavery were disposed to resist the interferences with State rights which the new proposal involved. In truth, slavery was more and more out of harmony with the new economic conditions which were rapidly taking complete control of the North and West, but had hardly been felt in the South. Thus the two sections, North and South, were more and more disposed to take opposite views of everything in which slavery was involved, and it had a faculty of involving itself in almost everything. The status of slavery in the Territories had been settled in 1820 (§197); that of slavery in the States had been settled by the constitution; but even in minor questions the intrusive element had to be reckoned with. The abolitionists sent their documents through the mails, and the South wished the Federal Government to interfere and stop the practice. The abolitionists persisted in petitioning Congress for the passage of various measures which Congress regarded as utterly unconstitutional; and the disposition of Congress to deny or regulate the right of petition in such matters excited the indignation of Northern men who had no sympathy with abolition. But the first occasion on which the views of the two sections came into flat contrast was on the question of the annexation of Texas.

221. The United States had had a vague claim to Texas until 1819, when the claim was surrendered to Spain in part compensation for Florida. On the revolt of Mexico, Texas became a part of that republic. It was colonized by Americans, mainly Southerners and slave-holders, and seceded from Mexico in 1835, defeating the Mexican armies and establishing its independence. Southern politicians desired its annexation to the United States for many reasons. Its people were kindred to them; its soil would widen the area of slavery; and its territory, it was hoped, could be divided into several States, to reinforce the Southern column in the senate. People in the North were either indifferent or hostile to the proposal; Van Buren had declared against it, and his action was the secret reason for his defeat in the Democratic convention. On the other hand, there were indications that the joint Oregon occupation of the Oregon country (§192) could not last much longer. American immigration into it had begun, while the Hudson's Bay Company, the English tenant of the soil, was the natural enemy of immigration. To carry the sentiment of both sections, the two points were coupled; and the Democratic convention declared for the reannexation of Texas and the reoccupation of Oregon.

222. One of the cardinal methods of the political abolitionists was to nominate candidates of their own against a doubtful friend, even though this secured the election of an open enemy. Clay's efforts to guard his Liberty condemnation of the Texas annexation project were just party enough to push the Liberty party, the political abolitionists, into voting for candidates of their own in New York; on a close vote their loss was enough to throw the electoral votes of that State to Polk, and its votes decided the result. Polk was elected (November 1844); and Texas was annexed to the United States in the following spring. At the next meeting of Congress (1845) Texas was admitted as a State.

Election
of 1844.
Admission
of
Texas.

223. West of Texas the northern prolongation of Mexico ran right athwart the westward movement of American population; and, though the movement had not yet reached the barrier, the Polk administration desired further acquisitions from Mexico. The western boundary of Texas was undefined; a strip of territory claimed by Texas was settled exclusively by Mexicans; but the Polk administration directed Taylor, the American commander in Texas, to cross the Nueces river and seize the disputed territory. Collisions with Mexican troops followed; they were beaten in the battles of Palo Alto and Resaca de la Palma, and were chased across the Rio Grande. Taylor followed, took the city of Monterey, and established himself far within northern Mexico.

224. On the news of the first bloodshed Congress declared war against Mexico, over the opposition of the Whigs. A land and naval force took possession of California, and a land expedition occupied New Mexico, so that the authority of Mexico over all the soil north of her present boundaries was abruptly terminated (1846). At the opening of 1847 Taylor fought the last battle in northern Mexico (Buena Vista), defeating the Mexicans, Buena and Scott, with a new army, landed at Vera Cruz for a march upon the city of Mexico. Scott's march was marked by one successful battle after another, usually against heavy odds; and in September he took the capital city and held it until peace was made (1848) by the treaty of Guadalupe Hidalgo. Among the terms of peace was the cession of the present State of California and the Territories of Utah, Arizona, and New Mexico, the consideration being a payment of \$15,000,000 by the United States and the assumption of some \$3,000,000 of debts due by Mexico to American citizens. With a subsequent rectification of frontier (1853), this cession added some

Vista.
Scott's
campaign.

500,000 square miles to the area of the United States; Texas itself made up some 375,000 square miles more. The settlement of the north-west boundary between Oregon and British Columbia (§ 221), giving its own share to each country (1846), with the Texas and Mexican cessions, gave the United States the complete territorial form retained until the annexation of Alaska in 1867.

Slavery in the new territory. 225. In the new territory slavery had been forbidden under Mexican law; and its annexation brought up the question of its status under American law. He who remembers the historical fact that slavery had never been more than a custom, ultimately recognized and protected by State law, will not have much difficulty in deciding about the propriety of forcing such a custom by law upon any part of a territory. But, if slavery was to be excluded from the new territory, the States which should ultimately be formed out of it would enter as free States, inclined to take an anti-slavery view of doubtful questions; and the influence of the South in the senate would be decreased. For the first time the South appears as a distinct *imperium in imperio* in the territorial difficulties which began in 1848.

"Squatter sovereignty." 226. The first appearance of these difficulties brought out in the Democratic party a solution which was so closely in line with the prejudices of the party, and apparently so likely to meet all the wishes of the South, that it bade fair to carry the party through the crisis without the loss of its Southern vote. This was "squatter sovereignty," the notion that it would be best for Congress to leave the people of each territory to settle the question of the existence of slavery for themselves. The broader and democratic ground for the party would have been that which it at first seemed likely to take—the "Wilmot proviso," a condition proposed to be added to the Act authorizing acquisitions of territory, providing that slavery should be forbidden in all territory to be acquired under the Act. In the end apparent expediency carried the dominant party off to "squatter sovereignty," and the Democratic adherents of the Wilmot proviso, with the Liberty party and the anti-slavery Whigs, united in 1848 under the name of the Free Soil party. The Whigs had no solution to offer; their entire programme, from this time to their downfall as a party, consisted in a persistent effort to evade or ignore all difficulties connected with slavery.

Wilmot proviso.

Free Soil party.

Election of 1848.

227. Taylor, after the battle of Buena Vista, resigned and came home, considering himself ill-used by the administration. He refused to commit himself to any party; and the Whigs were forced to accept him as their candidate in 1848. The Democrats nominated Cass; and the Free Soil party, or "Free-Soilers," nominated Van Buren. By the vote of the last-named party the Democratic candidate lost New York and the election, and Taylor was elected president. Taking office in 1849, he had on his shoulders the whole burden of the territorial difficulties, aggravated by the discovery of gold in California and the sudden rise of population there. Congress was so split into factions that it could for a long time agree upon nothing; thieves and outlaws were too strong for the semi-military government of California; and the people of that Territory, with the approval of the president, proceeded to form a constitution and apply for admission as a State. They had so framed their constitution as to forbid slavery; and this was really the application of the Wilmot proviso to the richest part of the new territory, and the South felt that it had been robbed of the cream of what it alone had fought cheerfully to obtain.

Admission of California.

228. The admission of California was not secured until September 1850, just after Taylor's sudden death, and then only by the addition of a bonus to Texas, the division of the rest of the Mexican cession into the Territories of

Utah and New Mexico without mention of slavery, and the passage of a Fugitive Slave Law. The slave trade, but not slavery, was forbidden in the District of Columbia. The whole was generally known as the compromise of 1850. ^{Compro-}Two of its features need notice. As has been said, slavery ^{mise of}was not mentioned in the Act; and the status of slavery ^{1850.}in the Territories was thus left uncertain. Congress can veto any legislation of a Territorial legislature, but, in fact, the two houses of Congress were hardly ever able to unite on anything after 1850, and both these Territories did establish slavery before 1860, without a Congressional veto. The advantage here was with the South. The other point, the Fugitive Slave Law, was a special demand ^{Fugitive}of the South. The constitution contained clauses directing ^{Slave}that fugitive criminals and slaves should be delivered up, ^{Law.}on requisition, by the State to which they had fled (§ 124). In the case of criminals the delivery was directed to be made by the executive of the State to which they had fled; in the case of slaves no delivering authority was specified, and an Act of Congress in 1793 had imposed the duty on Federal judges or on local State magistrates. Some of the States had passed "personal liberty laws," forbidding or ^{Personal}limiting the action of their magistrates in such cases; and ^{liberty}the Act of 1850 transferred the decision of such cases to ^{laws.}United States commissioners, with the assistance of United States marshals. It imposed penalties on rescues, and denied a jury trial. All the ill-effects of the law were not felt until a year or two of its operation had passed (§ 244).

229. The question of slavery had taken up so much time in Congress that its other legislation was comparatively limited. The rates of postage were reduced to five and ten cents for distances less and greater than 300 miles (1845); and the naval school at Annapolis was established the same year. The military school at West Point had been established in 1794. When the Democratic party had obtained complete control of the government, it re-established the "sub-treasury," or independent treasury (1846), which is still the basis of the treasury system. In ^{Tariff of}the same year, after an exhaustive report by Robert J. ^{1846.}Walker, Polk's secretary of the treasury, the tariff of 1846 was passed; it reduced duties, and cut out all forms of protection. With the exception of a slight additional reduction of duties in 1857, this remained in force until 1861.

230. Five States were admitted during the last ten ^{Admis-}years of this period,—Florida (1845), Texas (1845), Iowa ^{sion of}(1846), Wisconsin (1848), and California (1850). The ^{Florida,}early entrance of Iowa, Wisconsin, and Florida had been ^{Iowa,}due largely to Indian wars,—the Black Hawk war in Iowa ^{and Wis-}and Wisconsin (1832), and the Seminole war in Florida ^{consin.}(1835–37), after each of which the defeated Indians were compelled to cede lands as the price of peace. The extinction of Indian titles in northern Michigan brought about the discovery of the great copper fields of that region, whose existence had been suspected long before it could be proved. Elsewhere settlement followed the lines already marked out, except in the new possessions on the Pacific coast, whose full possibilities were not yet known. Railroads in the Eastern States were beginning to show ^{Railways}something of a connected system; in the South they had ^{and tele-}hardly changed since 1840; in the West they had only ^{graphs.}been prolonged on their original lines. The telegraph, which was to make man master of even the longest and most complicated systems, was brought into use in 1844; but it is not until the census of 1860 that its effects are seen in the fully connected network of railroads which then covers the whole North and West (§ 273).

231. The sudden development of wealth in the country ^{Inven-}gave an impetus to the spirit of invention. Goodyear's ^{tion.}method of vulcanizing rubber (1839) had come into use. M'Cormick had made an invention whose results have

been hardly less than that of the locomotive in their importance to the United States. He had patented a reaping-machine in 1834, and this, further improved and supplemented by other inventions, had brought into play the whole system of agricultural machinery whose existence was scarcely known elsewhere until the London "World's Fair" of 1851 brought it into notice. It was agricultural machinery that made Western farms profitable and enabled the railroads to fill the West so rapidly (§ 278). A successful sewing-machine came in 1846; the powerloom and the surgical use of anæsthetics in the same year; and the rotary press for printing in 1847.

232. All the conditions of life were changing so rapidly that it was natural that the minds of men should change with them or become unsettled. This was the era of new sects, of communities, of fantastic proposals of every kind, of transcendentalism in literature, religion, and politics. Not the most fantastic or benevolent, but certainly the most successful, of these was the sect of Mormons, or Latter-day Saints. They settled in the new Territory of Utah in 1847, calling their capital Salt Lake City, and spreading thence through the neighbouring Territories. There they have become a menace to the American system; their numbers are so great that it is against American instincts to deprive them of self-government and keep them under a Congressional despotism; while their polygamy and submission to their hierarchy make it impossible to erect them into a State which shall have complete control of marriage and divorce.

233. The material development of the United States since 1830 had been extraordinary, but every year made it more evident that the South was not sharing in it. It is plain now that the fault was in the labour system of the South: her only labourers were slaves, and a slave who was fit for anything better than field labour was *prima facie* a dangerous man. The process of divergence had as yet gone only far enough to awaken intelligent men in the South to the fact of its existence, and to stir them to efforts as hopeless as they were earnest, to find some artificial stimulus for Southern industries. In the next ten years the process was to show its effects on the national field.

IX. TENDENCIES TO DISUNION: 1850-61.

234. The abolitionists had never ceased to din the iniquity of slavery into the ears of the American people. Calhoun, Webster, and Clay, with nearly all the other political leaders of 1850, had united in deploring the wickedness of these fanatics, who were persistently stirring up a question which was steadily widening the distance between the sections. They mistook the symptom for the disease. Slavery itself had put the South out of harmony with its surroundings, and still more out of harmony with the inevitable lines of the country's development. Even in 1850, though they hardly yet knew it, the two sections had drifted so far apart that they were practically two different countries.

235. The case of the South was one of arrested development. The South remained very much as in 1790; while other parts of the country had developed, it had stood still. The remnants of colonial feeling, of class influence, which advancing democracy had wiped out elsewhere, retained all their force here, aggravated by the effects of an essentially aristocratic system of employment. The ruling class had to maintain a military control over the labouring class, and a class influence over the poorer whites. It had even secured in the constitution provision for its political power in the representation given to three-fifths of the slaves. The twenty additional members of the house of representatives were not simply a gain to the South; they were still more a gain to the "black districts," where whites

were few, and the slave-holder controlled the district. Slave-owners and slave-holders together, there were but 350,000 of them; but they had common interests, the intelligence to see them, and the courage to contend for them. The first step of a rising man was to buy slaves; and this was enough to enroll him in the dominant class. From it were drawn the representatives and senators in Congress, the governors, and all the holders of offices over which the "slave power," as it came to be called, had control. Not only was the South inert; its ruling class, its ablest and best men, were united in defence of tendencies which were alien and hostile to those of the rest of the country.

236. Immigration into the United States was not an important factor in its development until about 1847. The immigrants, so late as 1820, numbered but 8000 per annum; their number did not touch 100,000 until 1842, and then it fell for a year or two almost to half that number. In 1847 it rose again to 235,000, in 1849 to 300,000, and in 1850 to 428,000; all told, more than two and a quarter million persons from abroad settled in the United States between 1847 and 1854. Taking the lowest estimates—\$80 each for the actual amount of money brought in by immigrants, and \$800 each for their industrial value to the country,—the wealth-increasing influence of such a stream of immigration may be calculated. Its political effects were even greater, and were all in the same direction. Leaving out the dregs of the immigration, which settled down in the seaboard cities, its best part was a powerful nationalizing force. It had not come to any particular State, but to the United States; it had none of the traditional prejudices in favour of a State, but a strong feeling for the whole country; and the new feelings which it brought in must have had their weight not only on the gross mass of the people, but on the views of former leaders. And all the influences of this enormous immigration were confined to the North and West, whose divergence from the South thus received a new impetus. The immigration avoided slave soil as if by instinct. So late as 1880 the census reports that the Southern States, except Florida, Louisiana, and Texas, are "practically without any foreign element"; but it was only in 1850-60 that this differentiating circumstance began to show itself plainly. And, as the sections began to differ further in aims and policy, the North began to gain heavily in ability to ensure its success.

237. Texas was the last slave State ever admitted; and as it refused to be divided, the South had no further increase of numbers in the senate. Until 1850 the admission of a free State had been so promptly balanced by the admission of a slave State that the senators of the two sections had remained about equal in number; in 1860 the free States had 36 senators and the slave States only 30. As the representation in the house had changed from 35 free State and 30 slave State members in 1790 to 147 free State and 90 slave State in 1860, and as the electors are the sum of the numbers of senators and representatives, it is evident that political power had passed away from the South in 1850. If at any time the free States should unite they could control the house of representatives and the senate, elect the president and vice-president, dictate the appointment of judges and other Federal officers, and make the laws what they pleased. If pressed to it, they could even control the interpretation of the laws by the Supreme Court. No Federal judge could be removed except by impeachment (§ 121), but an Act of Congress could at any time increase the number of judges to any extent, and the appointment of the additional judges could reverse the opinion of the court. All the interests of the South depended on the one question whether the free States would unite or not.

Ten-
dencies
to dis-
union.

238. In circumstances so critical a cautious quiescence and avoidance of public attention was the only safe course for the "slave power," but that course had become impossible. The numbers interested had become too large to be subject to complete discipline; all could not be held in cautious reserve; and, when an advanced proposal came from any quarter of the slave-holding lines, the whole army was shortly forced up to the advanced position. Every movement of the mass was necessarily aggressive; and aggression meant final collision. If collision came, it must be on some question of the rights of the States; and on such a question the whole South would move as one man. Everything thus tended to disunion.

Sec-
tarian
divi-
sion.

239. The Protestant churches of the United States had reflected in their organization the spirit of the political institutions under which they lived. Acting as purely voluntary associations, they had been organized into governments by delegates, much like the "conventions" which had been evolved in the political parties (§ 203). The omnipresent slavery question intruded into these bodies, and split them. The Baptist Church was thus divided into a Northern and a Southern branch in 1845, and the equally powerful Methodist Church met the same fate the following year. Two of the four great Protestant bodies were thus no longer national; it was only by the most careful management that the integrity of the Presbyterian Church was maintained until 1861, when it also yielded; and only the Episcopal and Roman Catholic Churches retained their national character. If the process of disruption did not extend to other sects, it was because they were already mainly Northern or mainly Southern.

Party
changes.

240. The political parties showed the same tendency. Each began to shrivel up in one section or the other. The notion of "squatter sovereignty," attractive at first to the Western democracy, and not repudiated by the South, enabled the Democratic party to pass the crisis of 1850 without losing much of its Northern vote, while Southern Whigs began to drift in, making the party continually more pro-slavery. This could not continue long without beginning to decrease its Northern vote, but this effect did not become plainly visible until after 1852. The efforts of the Whig party to ignore the great question alienated its anti-slavery members in the North, while they did not satisfy its Southern members. The Whig losses were not at first heavy, but, as the electoral vote of each State is determined by the barest plurality of the popular vote, they were enough to defeat the party almost everywhere in the presidential election of 1852. The Whigs nominated Scott and the Democrats Pierce; and Pierce carried all but four of the thirty-one States, and was elected. This revelation of hopeless weakness was the downfall of the Whig party; it maintained its organization for four years longer, but the life had gone out of it. The future was with the Free Soil party, though it had polled but few votes in 1852.

Election
of 1852.

Changes
in leader-
ship.

241. During the administration of Taylor (and Vice-President Fillmore, who succeeded him) Clay, Webster, Calhoun, Polk, and Taylor were removed by death, and there was a steady drift of other political leaders out of public life. New men were pushing in everywhere, and in both sections they showed the prevailing tendency to disunion. The best of them were unprecedentedly radical. Sumner, Seward, and Chase came into the senate, bringing the first accession of recognized force and ability to the anti-slavery feeling in that body. The new Southern men, such as Davis, and the Democratic recruits from the Southern Whig party, such as Stephens, were ready to take the ground on which Calhoun had always insisted—that Congress was bound not merely to the negative duty of not attacking slavery in the Territories, but to the posi-

tive duty of protecting it. This, if it should become the general Southern position, was certain to destroy the notion of squatter sovereignty (§ 226), and thus to split the Democratic party, which was almost the last national ligament that now held the two fragments of the Union together.

242. The social disintegration was as rapid. Northern Social men travelling in the South were naturally looked upon with increasing suspicion, and were made to feel that they were on a soil alien in sympathies. Some of the worst phases of democracy were called into play in the South; and, in some sections, law openly yielded supremacy to popular passion in the cases of suspected abolitionists. Southern conventions, on all sorts of subjects, became common; and in these meetings, permeated by a dawning sense of Southern nationality, hardly any proposition looking to Southern independence of the North was met with disfavour. In State elections a distinctly disunion element appeared; and, though it was defeated, the majority did not deny the right of secession, only its expediency.

243. Calhoun, in his last and greatest speech, called attention to the manner in which one tie after another was snapping. But he ignored the real peril of the situation—its dangerous facts: that the South was steadily growing weaker in comparison with the North, and more unable to secure a wider area for the slave system; that it was therefore being steadily forced into demanding active Congressional protection for slavery in the Territories; that the North would never submit to this; and that the South must submit to the will of the majority or bring about a collision by attempting to secede.

244. Anti-slavery feeling in the North was stimulated by the manner in which the Fugitive Slave Law (§ 228) was enforced immediately after 1850. The chase after fugitive slaves was prosecuted in many cases with circumstances of revolting brutality, and features of the slave system which had been tacitly looked upon as fictitious were brought home to the heart of the free States. The added feeling showed its force when the Kansas-Nebraska Act was passed by Congress (1854). It organized the two new Territories of Kansas and Nebraska. Both of them were for ever free soil by the terms of the Missouri compromise (§ 197). But the success of the notion of squatter sovereignty in holding the Democratic party together while destroying the Whig party had intoxicated Douglas and other Northern Democrats; and they now applied the doctrine to these Territories. They did not desire "to vote slavery up or down," but left the decision to the people of the two Territories.

245. This was the grossest political blunder in American history. The status of slavery had been settled, by the constitution or by the compromises of 1820 and 1850, on every square foot of American soil; right or wrong, the settlement was made. The Kansas-Nebraska Act took a great mass of territory out of the settlement and flung it into the arena as a prize for which the sections were to struggle; and the struggle always tended to force, as the only arbiter. The first result of the Act was to throw parties into chaos. An American or "Know-Nothing" party, a secret oath-bound organization, pledged to oppose the influence or power of foreign-born citizens, had been formed to take the place of the defunct Whig party. It had been quite successful in State elections for a time, and was now beginning to have larger aspirations. It, like the Whig party, intended to ignore slavery, but, after a few years of life, the questions complicated with slavery entered its organization and divided it also. Even in 1854 many of its leaders in the North were forced to take position against the Kansas-Nebraska Act, while hosts of others joined in the opposition without any party organization. No American party ever rose so swiftly as

can
party."

The Republican party.

this latter ; with no other party name than the awkward title of "Anti-Nebraska men," it carried the Congressional elections of 1854 at the North, forced many of the former Know-Nothing leaders into union with it, and controlled the house of representatives of the Congress which met in 1855. The Democratic party, which had been practically the only party since 1852, had now to face the latest and strongest of its broad-constructionist opponents, one which with the nationalizing features of the Federal and Whig parties combined democratic feelings and methods, and, above all, had a democratic purpose at bottom. It acknowledged, at first, no purpose aimed at slavery, only an intention to exclude slavery from the Territories ; but, under such principles, it was the only party which was potentially an anti-slavery party, the only party to which the enslaved labourer of the South could look with the faintest hope of aid in reaching the status of a man. The new party had grasped the function which belonged of right to its great opponent, and it seized with it its opponent's original title. The name Democrat had quite taken the place of that first used—Republican (§ 150), but the latter had never passed out of popular remembrance and liking at the North. The new party took quick and skilful advantage of this by assuming the old name, and early in 1856 the two great parties of the next thirty years—the Democratic and Republican parties—were drawn up against one another.

Koszta case.

Japan.

Ostend manifesto. Filibustering.

Kansas.

246. The foreign relations of the United States during Pierce's term of office were overshadowed by the domestic difficulties, but were of importance. In the Koszta case (1853) national protection had been afforded on foreign soil to a person who had only taken the preliminary steps to naturalization. Japan had been opened to American intercourse and commerce (1854). But the question of slavery was more and more thrusting itself even into foreign relations. A great Southern republic, to be founded at first by the slave States, but to take in gradually the whole territory around the Gulf of Mexico and include the West Indies, was soon to be a pretty general ambition among slave-holders, and its first phases appeared during Pierce's administration. Efforts were begun to obtain Cuba from Spain ; and the three leading American ministers abroad, meeting at Ostend, united in declaring the possession of Cuba to be essential to the well-being of the United States (1854). "Filibustering" expeditions against Cuba or the smaller South American states, intended so to revolutionize them as to lay a basis for an application to be annexed to the United States, became common, and taxed the energies of the Federal Government for their prevention. All these, however, yielded in interest and importance to the affairs in Kansas.

247. Nebraska was then supposed to be a desert, and attention was directed almost exclusively to Kansas. No sooner had its organization left the matter of slavery to be decided by its "people" than the anti-slavery people of the North and West felt it to be their duty to see that the "people" of the Territory should be anti-slavery in sympathy. Emigrant associations were formed, and these shipped men and families to Kansas, arming them for their protection in the new country. Southern newspapers called for similar measures in the South, but the call was less effective. Southern men without slaves, settling a new State, were uncomfortably apt to prohibit slavery, as in California. Only slave-holders were trusty pro-slavery men ; and such were not likely to take slaves to Kansas, and risk their ownership on the result of the struggle. But for the people of Missouri, Kansas would have been free soil at once. Lying across the direct road to Kansas, the Missouri settlers blockaded the way of free-State settlers, crossed into Kansas, and voted profusely at

the first Territorial election. Their votes chose a Territorial legislature which gave a complete code of slave laws to the Territory. Passing to the north of Missouri the "free-State settlers" entered Kansas to find that their opponents had secured the first position. This brought out the fundamental difference between a Territory—under the absolute control of Congress and only privileged in certain branches of legislation—and a State with complete jurisdiction over its own affairs. Finding themselves cut off from control of the former, the free-State settlers determined to attempt to substitute the latter. They organized a State government (1855), and applied for admission by Congress. Such irregular erections of States had been known before ; and, though they were confessedly not binding until confirmed by Congress, the Democratic party had always been tender with them, and prone to seek a compromise with them. A symptom of the process which had been making the Democratic party pro-slavery was seen in the attitude which the Democratic administration now took towards the inchoate State of Kansas. Never thinking of compromise, it pounced on the new organization, scattered it, arrested its leaders, and expressed a hesitating desire to try them for treason (1856). Nevertheless, the free-State settlers gave no further obedience to the Territorial government, as the pro-slavery settlers refused to recognize the pseudo-State government, and the struggle passed into a real civil war, the two powers mustering considerable armies, fighting battles, capturing towns, and paroling prisoners. The struggle was really over in 1857, and the South was beaten. It could not compete with the resources and enthusiasm of the other section ; its settlers were not unanimous, as their opponents were ; and the anti-slavery settlers were in a great majority. There were, however, all sorts of obstacles yet to be overcome before the new State of Kansas was recognized by Congress, after the withdrawal of the senators of the seceding States (1861).

Free-State government.

248. In the heat of the Kansas struggle came the Election of 1856. The Democrats nominated Buchanan, declaring, as usual, for the strictest limitation of the powers of the Federal Government on a number of points specified, and reaffirming the principle of the Kansas-Nebraska Act—the settlement of slavery by the people of the Territory. The remnant of the Whig party, including the Know-Nothings of the North and those Southern men who wished no further discussion of slavery, nominated the president who had gone out of office in 1853, Fillmore. The Republican party nominated Fremont ; the bulk of its manifesto was taken up with protests against attempts to introduce slavery into the Territories ; but it showed its broad-construction tendencies by declaring for appropriations of public moneys for internal improvements. The Democrats were successful in electing Buchanan ; but the position of the party was quite different from the triumph with which it had come out of the election of 1852. It was no longer master of twenty-seven of the thirty-one States ; all New England and New York, all the North-West but Indiana and Illinois, all the free States but five, had gone against it ; its candidate no longer had a majority of the popular vote, but was chosen by a majority of the electoral votes ; and it had before it a party with nearly as many popular votes as its own, the control of most of the strongest section of the Union, and an enthusiasm which was more dangerous still. For the first time in the history of the country a distinctly anti-slavery candidate had obtained an electoral vote, and had even come near obtaining the presidency. Fillmore had carried but one State, Maryland ; Buchanan had carried the rest of the South, with a few States in the North, and Fremont the rest of the North and none of the South.

If things had gone so far that the two sections were to be constituted into opposing political parties, it was evident that the end was near.

The
Dred
Scott
decision.

249. Oddly enough, the constitutionality of the compromise of 1820 (§ 197) had never happened to come before the Supreme Court for consideration. In 1856-57 it came up for the first time. One Dred Scott, a Missouri slave who had been taken to the Territory covered by the compromise, and had therefore sued for his freedom, was sold to a citizen of another State. Scott then transferred his suit from the State to the Federal courts, under the power given to them to try suits between citizens of different States, and the case came by appeal to the Supreme Court. Its decision was announced at the beginning of Buchanan's administration. It put Scott out of court on the ground that a slave, or the descendant of slaves, could not be a citizen of the United States or have any standing in Federal courts. The opinion of the chief-justice went on to attack the validity of the Missouri compromise, for the reasons that one of the constitutional functions of Congress was the protection of property; that slaves had been recognized as property by the constitution; and that Congress was bound to protect, not to prohibit, slavery in the Territories. The mass of the Northern people held that slaves were looked on by the constitution, not as property, but as "persons held to service or labour" by State laws; that the constitutional function of Congress was the protection of liberty as well as property; and that Congress was thus bound to prohibit, not to protect, slavery in the Territories. Another step in the road to disunion was thus taken, as the only peaceful interpreter of the constitution was pushed out of the way. The North flouted the decision of the Supreme Court, and the storm of angry dissent which it aroused did the disunionists good service at the South. From this time the leading newspapers in the South maintained that the radical Southern view first advanced by Calhoun, and but slowly accepted by other Southern leaders, as to the duty of Congress to protect slavery in the Territories, had been confirmed by the Supreme Court; that the Northern Republicans had rejected it; and that even the squatter sovereignty theory of Northern Democrats could no longer be submitted to by the South.

Admission of
Minnesota and
Oregon.

250. The population of the United States in 1860 was over 31,000,000, an increase of more than 8,000,000 in ten years. As the decennial increases of population became larger, so did the divergence of the sections in population, and still more in wealth and resources. Two more free States came in during this period—Minnesota (1858) and Oregon (1859),—and Kansas was clamouring loudly for the same privilege. The free and slave States, which had been almost equal in population in 1790, stood now as 19 to 12. And of the 12,000,000 in slave States, the 4,000,000 slaves and the 250,000 free blacks were not so much a factor of strength as a possible source of weakness and danger. No serious slave rising had ever taken place in the South; but the sudden flaming out of John Brown's insurrection (1859), and the alarm which it carried through the South, were tokens of a danger which added a new horror to the chances of civil war. It was not wonderful that men, in the hope of finding some compromise by which to avoid such a catastrophe, should be willing to give up everything but principle and even to trench sharply upon principle itself, nor that offers of compromise should urge Southern leaders farther into the fatal belief that "the North would not fight."

John
Brown's
raid.

251. Northern Democrats, under the lead of Douglas, had been forced already almost to the point of revolt by the determination of Southern senators to prevent the admission of Kansas as a free State, if not to secure her

admission as a slave State. When the Democratic convention of 1860 met at Charleston, the last strand of the last national political organization parted; the Democratic party itself was split at last by the slavery question. The Southern delegates demanded a declaration in favour of the duty of Congress to protect slavery in the Territories. It was all that the Douglas Democrats could then do to maintain themselves in a few Northern States; such a declaration meant political suicide everywhere, and they voted it down. The convention divided into two bodies. The Southern body adjourned to Richmond, and the Northern and border State convention to Baltimore. Here the Northern delegates, by seating some delegates friendly to Douglas, provoked a further secession of border State delegates, who, in company with the Richmond body, nominated Breckinridge (p. 788) and Lane for president and vice-president. The remainder of the original convention nominated Douglas and H. V. Johnson.

252. The remnant of the old Whig and Know-Nothing parties, now calling itself the Constitutional Union party, met at Baltimore and nominated Bell (p. 788) and Everett. The Republican convention met at Chicago. Its "platform" of 1856 had been somewhat broad constructionist in its nature and leanings, but a strong Democratic element in the party had prevented it from going too far in this direction. The election of 1856 had shown that, with the votes of Pennsylvania and Illinois, the party would then have been successful, and the Democratic element was now ready to take almost anything which would secure the votes of these States. This state of affairs will go to explain the nomination of Lincoln, of Illinois, for president, with Hamlin, a former Democrat, for vice-president, and the declaration of the platform in favour of a protective tariff. The mass of the platform was still devoted to the necessity of excluding slavery from the Territories. To sum up: the Bell party wished to have no discussion of slavery; the Douglas Democrats rested on squatter sovereignty and the compromise of 1850, but would accept the decision of the Supreme Court; the Republicans demanded that Congress should legislate for the prohibition of slavery in the Territories; and the Southern Democrats demanded that Congress should legislate for the protection of slavery in the Territories.

The
parties
and
slavery
in the
Territories.

253. No candidate received a majority of the popular vote, Lincoln standing first and Douglas second. But Lincoln and Hamlin had a clear majority of the electoral vote, and so were elected, Breckinridge and Lane coming next. It is worthy of mention that, up to the last hours of Lincoln's first term of office, Congress would always have contained a majority opposed to him but for the absence of the members from the seceding States. The interests of the South and even of slavery were thus safe enough under an anti-slavery president. But the drift of events was too plain. Nullification had come and gone, and the nation feared it no longer. Even secession by a single State was now almost out of the question; the letters of Southern governors in 1860, in consultation on the state of affairs, agree that no State would secede without assurances of support by others. If this crisis were allowed to slip by without action, even a sectional secession would soon be impossible. If secession were a right, it must be asserted now or never.

Election
of 1860.

254. Some assurance of united action must have been obtained, for South Carolina ventured into secession. The democratic revolution which, since 1829, had compelled the legislatures to give the choice of presidential electors (§ 119) to the people of the States had not affected South Carolina; her electors were still chosen by the legislature. That body, on the election day of November, 1860, having chosen the State's electors,

Secession.

remained in session until the telegraph had brought assurances that Lincoln had secured a sufficient number of electors to ensure his election; it then summoned a State convention and adjourned. The State convention, which is a legislative body chosen for a special purpose, met December 20, and unanimously passed an "ordinance of secession," repealing the Acts by which the State had ratified the constitution and its amendments (§ 108), and dissolving "the Union now subsisting between South Carolina and other States, under the name of the United States of America." The convention took all steps necessary to make the State ready for war, and adjourned. Similar ordinances were passed by conventions in Mississippi (January 9, 1861), Florida (January 10), Alabama (January 11), Georgia (January 18), Louisiana (January 23), and Texas (February 1).

The argument for secession.

255. The opposition in the South did not deny the right to secede, but the expediency of its exercise. Their effort was to elect delegates to the State conventions who would vote not to secede. They were beaten, says A. H. Stephens, by the cry that the States "could make better terms out of the Union than in it." That is, the States were to withdraw individually, suspend the functions of the Federal Government within their jurisdiction for the time, consider maturely any proposals for guarantees for their rights in the Union, and return as soon as satisfactory guarantees should be given. A second point to be noted is the difference between the notions of a State convention prevalent in the North and in the South. The Northern State convention was generally considered as a preliminary body, whose action was not complete or valid until ratified by a popular vote. The Southern State convention was looked upon as the incarnation of the sovereignty of the State, and its action was not supposed to need a popular ratification. When the conventions of the seceding States had adopted the ordinances of secession, they proceeded to other business. They appointed delegates, who met at Montgomery, the capital of Alabama, February 4, formed a provisional constitution for the "Confederate States," chose a provisional president and vice-president (Jefferson Davis and A. H. Stephens), and established an army, treasury, and other executive departments. The president and vice-president were inaugurated February 18. The permanent constitution, adopted in March, was copied from that of the United States, with variations meant to maintain State sovereignty, to give the cabinet seats in Congress, to prevent the grant of bounties or any protective features in the tariff or the maintenance of internal improvements at general expense, and to "recognize and protect" "the institution of negro slavery, as it now exists in the Confederate States."

Action at the State conventions.

The "Confederate States."

Constitutional rights.

256. Under what claim of constitutional right all this was done passes comprehension. That a State convention should have the final power of decision on the question which it was summoned to consider is quite as radical doctrine as has yet been heard of; that a State convention, summoned to consider the one question of secession, should go on, with no appeal to any further popular authority or mandate, to send delegates to meet those of other States and form a new national government, which could only exist by warring on the United States, is a novel feature in American constitutional law. It was revolution or nothing. Only in Texas, where the call of the State convention was so irregular that a popular vote could hardly be escaped, was any popular vote allowed. Elsewhere, the functions of the voter ceased when he voted for delegates to the State convention; he could only look on helplessly while that body went on to constitute him a citizen of a new nation of which he had not dreamed when he voted.

257. The border States were in two tiers—North Carolina, Tennessee, and Arkansas next to the seceding States, and Delaware, Maryland, Virginia, Kentucky, and Missouri next to the free States. None of these were willing to secede. There was, however, one force which might draw them into secession. A State which did not wish to secede, but believed in State sovereignty and the abstract right of secession, would be inclined to take up arms to resist any attempt by the Federal Government to coerce a seceding State. In this way, in the following spring, the original seven seceding States were reinforced by four of the border States (§ 267), making their final number eleven.

258. In the North and West surprisingly little attention was given to the systematic course of procedure along the Gulf. The people of those sections were very busy; they had heard much of this talk before, and looked upon it as a kind of stage-thunder, the inevitable accompaniment of recent presidential elections; and they expected the difficulty to be settled in some way. Republican politicians, with the exception of a few, were inclined to refrain from public declarations of intention. Some of them, such as Seward, showed a disposition to let the "erring sisters" depart in peace, expecting to make the loss good by accessions from Canada. A few, like Chandler, believed that there would be "blood-letting," but most of them were still doubtful as to the future. Democratic politicians were hide-bound by their repetition of the phrase "voluntary Union" (§ 180); they had not yet hit upon the theory which carried the War Democrats through the final struggle, that the sovereign State of New York could make war upon the sovereign State of South Carolina for the unfriendly act of secession, and that the war was waged by the non-seceding against the seceding States. President Buchanan publicly condemned the doctrine of secession, though he added a confession of his inability to see how secession was to be prevented if a State should be so wilful as to attempt it. Congress did nothing, except to admit Kansas as a free State and adopt the protective Morrill tariff (§ 276); even after its members from the seceding States had withdrawn, those who remained made no preparations for conflict, and, at their adjournment in March 1861, left the Federal Government naked and helpless before its enemies.

259. The only sign of life in the body politic, the half-awakened word of warning from the democracy of the North and West, was its choice of governors of States. A remarkable group of men, soon to be known as the "war governors,"—Washburn of Maine, Fairbanks of Vermont, Goodwin of New Hampshire, Andrew (p. 787) of Massachusetts, Sprague of Rhode Island, Buckingham (p. 788) of Connecticut, Morgan (p. 790) of New York, Olden of New Jersey, Curtin of Pennsylvania, Dennison of Ohio, Morton (p. 790) of Indiana, Yates of Illinois, Blair of Michigan, Randall of Wisconsin, Kirkwood of Iowa, and Ramsey of Minnesota,—held the executive powers of the Northern States in 1861-62. Some of these governors, such as Andrew and Buckingham, as they saw the struggle come nearer, went so far as to order the purchase of warlike material for their States on their private responsibility, and their action saved days of time. And at all times they were admirably prompt, methodical, clear-sighted, and intensely devoted to their one duty.

260. The little army of the United States had been almost put out of consideration; wherever its detachments could be found in the South they were surrounded and forced to surrender and to be transferred to the North. After secession, and in some of the States even before it, the forts, arsenals, mints, custom-houses, ship-yards, and public property of the United States had been seized by

States
property.

authority of the State, and these were held until transferred to the new Confederate States organization. In the first two months of 1861 the authority of the United States was paralysed in seven States, and in at least seven more its future authority seemed of very doubtful duration.

Position
of the
remain-
ing forts.

261. Only a few forts, of all the magnificent structures with which the nation had dotted the Southern coast, remained to it—the forts near Key West, Fortress Monroe at the mouth of Chesapeake Bay, Fort Pickens at Pensacola, and Fort Sumter in Charleston harbour. Both the last-named were beleaguered by hostile batteries, but the administration of President Buchanan, intent on maintaining the peace until the new administration should come in, instructed their commanding officers to refrain from any acts tending to open conflict. The Federal officers, therefore, were obliged to look idly on while every preparation was made for their destruction, and even while a vessel bearing supplies for Fort Sumter was driven back by the batteries between it and the sea.

Slavery
and dis-
union.

262. The divergence between the two sections of the country had thus passed into disunion, and was soon to pass into open hostility. The legal recognition of the custom of slavery, acting upon and reacted upon by every step in their economic development and every difference in their natural characteristics, surroundings, and institutions, had carried North and South further and faster apart, until the elements of a distinct nationality had appeared in the latter. Slavery had had somewhat the same effect on the South that democracy had had on the colonies. In the latter case the aristocracy of the mother country had made a very feeble struggle to maintain the unity of its empire. It remained to be seen, in the American case, whether democracy would do better.

X. THE CIVIL WAR: 1861-65.

Embar-
rassments
of the
Govern-
ment.

263. Secession had taken away many of the men who had for years managed the Federal Government, and who understood its workings. Lincoln's party was in power for the first time; his officers were new to the routine of Federal administration; and the circumstances with which they were called upon to deal were such as to daunt any spirit. The Government had become so nearly bankrupt in the closing days of Buchanan's administration that it had only escaped by paying double interest, and that by the special favour of the New York banks, which obtained in return the appointment of Dix as secretary of the treasury. The army had been almost broken up by captures of men and material and by resignations of competent and trusted officers. The navy had come to such a pass that, in February 1861, a house committee reported that only two vessels, one of twenty, the other of two guns, were available for the defence of the entire Atlantic coast. And, to complicate all difficulties, a horde of clamorous office-seekers crowded Washington.

Surrender
of Fort
Sumter.
Rising
in the
North.

264. Before many weeks of Lincoln's administration had passed, the starting of an expedition to provision Fort Sumter brought on an attack by the batteries around the fort, and, after a bombardment of 36 hours, the fort surrendered (April 14, 1861). It is not necessary to rehearse the familiar story of the outburst of feeling which followed this event and the proclamation of President Lincoln calling for volunteers, the mustering of men, the eagerness of States, cities, and villages to hurry volunteers forward and to supply money to their own Government in its need. The 75,000 volunteers called for were supplied three or four times over, and those who were refused felt the refusal as a personal deprivation.

265. There had been some belief in the South that the North-West would take no part in the impending conflict,

and that its people could be persuaded to keep up friendly relations with the new nationality until the final treaty of peace should establish all the fragments of the late Union upon an international basis. In the spring months of 1861 Douglas, who had long been denounced as the tool of the Southern slave-holders, was spending the closing days of life in expressing the determination of the North-West that it would never submit to have "a line of custom-houses" between it and the ocean. The batteries which Confederate authority was erecting on the banks of the Mississippi were fuel to the flame. Far-off California, which had been considered neutral by all parties, pronounced as unequivocally for the national authority.

266. The shock of arms put an end to opposition in the South as well. The peculiar isolation of life in the South precluded the more ignorant voter from any comparisons of the power of his State with any other; to him it was almost inconceivable that his State should own or have a superior. The better educated men, of wider experience, had been trained to think State sovereignty the foundation of civil liberty, and, when their State spoke, they felt bound to "follow their State." The president of the Confederate States issued his call for men, and it was also more than met. On both sides of the line armed men were hurrying to a meeting.

267. Lincoln's call for troops met with an angry reception wherever the doctrine of State sovereignty had a foothold. The governors of the border States (§ 257) generally returned it with a refusal to furnish any troops. Two States, North Carolina and Arkansas, seceded and joined the Confederate States. In two others, Virginia and Tennessee, the State politicians formed "military leagues" with the Confederacy, allowing Confederate troops to take possession of the States, and then submitted the question of secession to "popular vote." The secession of these States was thus accomplished, and Richmond became the Confederate capital. The same process was attempted in Missouri, but failed, and the State remained loyal. The politician class in Maryland and Kentucky took the extraordinary course of attempting to maintain neutrality; but the growing power of the Federal Government soon enabled the people of the two States to resume control of their governments and give consistent support to the Union. Kentucky, however, had troops in the Confederate armies; and one of her citizens, the late vice-president, John C. Breckinridge, left his place in the senate and became an officer in the Confederate service. Delaware cast her lot from the first with the Union.

268. The first blood of the war was shed in the streets of Baltimore, when a mob attempted to stop Massachusetts troops on their way to Washington (April 19). For a time there was difficulty in getting troops through Maryland because of the active hostility of a part of its people, but this was overcome, and the national capital was made secure. The Confederate lines had been pushed up to Manassas Junction, about 30 miles from Washington. When Congress, called into special session by the president for July 4, came together, the outline of the Confederate States had been fixed. Their line of defence held the left bank of the Potomac from Fortress Monroe nearly to Washington; thence, at a distance of some 30 miles from the river, to Harper's Ferry; thence through the mountains of western Virginia and the southern part of Kentucky, crossing the Mississippi a little below Cairo; thence through southern Missouri to the eastern border of Kansas; and thence south-west through the Indian Territory and along the northern boundary of Texas to the Rio Grande. The length of the line, including also the Atlantic and Gulf coasts, has been estimated at 11,000 miles. The territory within it comprised about 800,000

The
blockade.

square miles, with a population of over 9,000,000 and great natural resources. Its cotton was almost essential to the manufactories of the world; in exchange for it every munition of war could be procured; and it was hardly possible to blockade a coast over 3000 miles in length, on which the blockading force had but one port of refuge, and that about the middle of the line. Nevertheless President Lincoln issued his proclamation announcing the blockade of the Southern coast, a proclamation from President Davis appearing with it, offering letters of marque and reprisal against the commerce of the United States to private vessels. The news brought out proclamations of neutrality from Great Britain and France, and, according to subsequent decisions of the Supreme Court, made the struggle a civil war, though the minority held that this did not occur legally until the Act of Congress of July 13, 1861, authorizing the president, in case of insurrection, to shut up ports and suspend commercial intercourse with the inhabitants of the revolted district.

Suspension of
habeas
corpus.

269. The president found himself compelled to assume powers never granted to the executive authority, trusting to the subsequent action of Congress to validate his action. He had to raise and support armies and navies; he even had to authorize seizures of necessary property, of railroad and telegraph lines, arrests of suspected persons, and the suspension of the writ of *habeas corpus* in certain districts. Congress supported him, and proceeded in 1863 to give the president power to suspend the writ anywhere in the United States, which he proceeded to do (§ 115). The Supreme Court, after the war, decided that no branch of the Government had power to suspend the writ in districts where the courts were open,—that the *privilege* of the writ might be suspended as to persons properly involved in the war, but that the writ was still to issue, the court deciding whether the person came within the classes to whom the suspension applied. This decision, however, did not come until “arbitrary arrests,” as they were called, had been a feature of the entire war. A similar suspension of the writ took place in the Confederate States.

Congress. 270. When Congress met (July 4, 1861), the absence of Southern members had made it heavily Republican. It decided to consider no business but that connected with the war, authorized a loan and the raising of 500,000 volunteers, and made confiscation of property a penalty of rebellion. While it was in session the first serious battle of the war—Bull Run, or Manassas—took place (July 21), and resulted in the defeat of the Federal army. Both armies were as yet so ill-trained that the victors gained nothing from their success. In the west the battle of Wilson's Creek, near Springfield, Mo. (August 10), was either a drawn battle or a Confederate victory; but here also the victors rather lost than gained ground after it. The captures of Fort Hatteras, N.C. (August 29), and Port Royal, S.C. (November 7), gave the blockading fleets two important harbours of refuge. The over-zealous action of a naval officer in taking the Confederate envoys Mason and Slidell out of a British mail-steamer sailing between two neutral ports almost brought about a collision between the United States and Great Britain in November. But the American precedents were all against the United States (§ 172), and the envoys were given up.

Army
of the
Potomac.

271. General M'Clellan (p. 789), in the early months of the war, had led a force of Western troops across the Ohio river, entered western Virginia, and beaten the Confederate armies in several battles. After the battle of Bull Run he was called to Washington and put in command of all the armies on the retirement of Scott. His genius for organization, and the unbounded confidence of the people in him, enabled him to form the troops at

and near Washington into the first great army of the war—the army of the Potomac. It was held, however, too much in idleness to suit the eagerness of the people and the administration; and the dissatisfaction grew louder as the winter of 1861–62 passed away without any forward movement (§ 284).

272. If the army was idle, Congress was not. The broad-construction tendencies of the party showed themselves more plainly as the war grew more serious; there was an increasing disposition to cut every knot by legislation, with less regard to the constitutionality of the legislation. A paper currency, commonly known as “green-Paper backs,” was adopted and made legal tender (February 25, 1862). The first symptoms of a disposition to attack slavery appeared: slavery was prohibited in the District of Columbia and the Territories; the army was forbidden to surrender escaped slaves to their owners; and slaves of insurgents were ordered to be confiscated. In addition to a Homestead Act, giving public lands to actual settlers at reduced rates (§ 200), Congress began a further development of the system of granting public lands to railway corporations.

273. The railway system of the United States was but twenty years old in 1850 (§ 230), but it had begun to assume some consistency. The day of short and disconnected lines had passed, and the connexions which were to develop into railway systems had appeared. Consolidation of smaller companies had begun; the all-rail route across the State of New York was made up of more than a dozen original companies at its consolidation in 1853. The Erie Railway was formed in 1851; and another western route—the Pennsylvania—was formed in 1854. These were at least the germs of great trunk lines (§ 312). The cost of American railways has been only from one-half to one-fourth of the cost of European railways; but an investment in a far western railway in 1850–60 was an extra-hazardous risk. Not only did social conditions make any form of business hazardous; the new railway often had to enter a territory bare of population, and there create its own towns, farms, and traffic. Whether it could do so was so doubtful as to make additional inducements to capital necessary. The means attempted by Congress in 1850, in the case of the Illinois Central Railroad, was to grant public lands to the corporation, reserving to the States the alternate sections. The expectation was that the railway, for the purpose of building up traffic, would sell lands to actual settlers at low rates, and that the value of the reserved lands would thus be increased. At first grants were made to the States for the benefit of the corporations; the Act of 1862 made the grant directly to the corporation.

274. The vital military and political necessity of an immediate railway connexion with the Pacific coast was hardly open to doubt in 1862; but the necessity hardly justified the terms which were offered and taken. The Union Pacific Railroad was incorporated; the United States Government was to issue to it bonds, on the completion of each 40 miles, to the amount of \$16,000 per mile, to be a first mortgage; through Utah and Nevada, the aid was to be doubled, and for some 300 miles of mountain building to be trebled; and, in addition to this, alternate sections of land were granted. The land-grant system, thus begun, was carried on in the cases of a large number of other roads, the largest single grants being those of 47,000,000 acres to the Northern Pacific (1864) and of 42,000,000 to the Atlantic and Pacific line (1866).

275. Specie payments had been suspended almost everywhere towards the end of 1861; but the price of gold was but 102·5 at the beginning of 1862. About May its price in paper currency began to rise. It touched 170 during

the next year, and 285 in 1864; but the real price probably never went much above 250. As gold rose, specie disappeared. Other articles felt the influence in currency prices. Mr D. A. Wells, in 1866, estimated that prices and rents had risen 90 per cent. since 1861, while wages had not risen more than 60 per cent.

Tariff and internal revenue taxation. 276. The duties on imports were driven higher than the Morrill tariff had ever contemplated (§ 258). The average rates, which had been 18 per cent. on dutiable articles and 12 per cent. on the aggregate in 1860-61, rose, before the end of the war, to nearly 50 per cent. on dutiable articles and 35 per cent. on the aggregate. Domestic manufactures sprang into new life under such hothouse encouragement; every one who had spare wealth converted it into manufacturing capital. The probability of such a result had been the means of getting votes for an increased tariff; free-traders had voted for it as well as protectionists. For the tariff was only a means of getting capital into positions in which taxation could be applied to it, and the "internal revenue" taxation was merciless beyond precedent. The annual increase of wealth from capital was then about \$550,000,000; the internal revenue taxation on it rose in 1866 to \$310,000,000, or nearly 60 per cent. Even after the war the taxation was kept up unflinchingly until the reduction of the national debt had brought it to a point where it was evidently at the mercy of time (§ 322).

Bonds. 277. The stress of all this upon the poor must have been great, but it was relieved in part by the bond-system on which the war was conducted (§ 322). While the armies and navies were shooting off large blocks of the crops of 1880 or 1890, work and wages were abundant for all who were competent for them. It is true, then, that the poor paid most of the cost of the war; it is also true that the poor had shared in that anticipation of the future which had been forced on the country, and that, when the drafts on the future came to be redeemed, it was done mainly by taxation on luxuries. The destruction of a Northern railroad meant more work for Northern iron mills and their workmen. The destruction of a Southern road was an unmitigated injury; it had to be made good at once, by paper issues; the South could make no drafts on the future, by bond issues, for the blockade had put cotton out of the game, and Southern bonds were hardly saleable. Every expense had to be met by paper issues; each issue forced prices higher; every rise in prices called for an increased issue of paper, with increased effects for evil. *A Rebel War-Clerk's Diary* gives the following as the prices in the Richmond market for May 1864:—"Boots, \$200; coats, \$350; pantaloons, \$100; shoes, \$125; flour, \$275 per barrel; meal, \$60 to \$80 per bushel; bacon, \$9 per pound; no beef in market; chickens, \$30 per pair; shad, \$20; potatoes, \$25 per bushel; turnip greens, \$4 per peck; white beans, \$4 per quart or \$120 per bushel; butter, \$15 per pound; lard same; wood, \$50 per cord." How the rise in salaries and wages, always far slower than other prices, could meet such prices as these, one must be left to imagine. It can only be said that most of the burden was really sustained by the women of the South.

Manufactures. 278. The complete lack of manufactures told heavily against the South from the beginning. As men were drawn from agriculture in the North and West, the increased demand for labour was shaded off into an increased demand for agricultural machinery (§ 231); every increased percentage of power in reaping-machines liberated so many men for service at the front. The reaping-machines of the South—the slaves—were incapable of any such improvement, and, besides, required the presence of a portion of the possible fighting-men at home to watch

them. There is an evident significance in the exemption from military duty in the Confederate States of "one agriculturist on such farm, where there is no white male adult not liable to duty, employing 15 able-bodied slaves between ten and fifty years of age." But, to the honour of the enslaved race, no insurrection took place.

279. The pressing need for men in the army made the Confederate Congress utterly unable to withstand the rate of growth of executive power. Its bills were prepared by the cabinet, and the action of Congress was quite perfunctory. The suspension of the writ of *habeas corpus*, and the vast powers granted to President Davis, or assumed by him under the plea of military necessity, with the absence of a watchful and well-informed public opinion, made the Confederate Government by degrees almost a despotism. It was not until the closing months of the war that the expiring Confederate Congress mustered up courage enough to oppose the president's will. The organized and even radical opposition to the war in the North, the meddlesomeness of Congress and its "committees on the conduct of the war," were no doubt unpleasant to Lincoln; but they carried the country through the crisis without the effects visible in the South.

280. Another act of Federal legislation—the National Bank Act—should be mentioned here, as it was closely connected with the sale of bonds (February 25, 1863). The banks were to be organized, and, on depositing United States bonds at Washington, were to be permitted to issue notes up to 90 per cent. of the value of the bonds deposited. As the redemption of the notes is thus assured, they circulate without question all over the United States. By a subsequent Act the remaining State bank circulation was taxed out of existence. The national banks are still in operation; but the disappearance of United States bonds threatens their continuance.

281. At the beginning of 1862 the lines of demarcation between the two powers had become plainly marked. The western part of Virginia had separated itself from the parent State, and was admitted as a State (1863) under the name of West Virginia. It was certain that Delaware, Maryland, Kentucky, and Missouri had been saved to the Union, and that the battle was to be fought out in the territory to the south of them. In the west Grant (p. 788), commanding a part of Buell's general forces, moved up the Tennessee river and broke the centre of the long Confederate line by the capture of Forts Henry and Donelson (February 1862). The collapse of the Confederate line opened the way for the occupation of almost all western Tennessee, including its capital, and the theatre of war was moved far forward to the southern boundary of the State, an advance of fully 200 miles into the heart of the Confederacy. It had been shown already that the successful officers were to be those from West Point; but even they were getting their first experience in the handling of large masses of men. Grant and Sherman owed a part of that experience to the military genius of the Confederate commander, Albert S. Johnston, whose sudden attack on their army at Pittsburgh Landing (April 6) brought on the first great battle of the war. The Federal forces held out stubbornly until the arrival of Buell's advance guard relieved the pressure, and the Confederates were driven back to Corinth, with the heavy loss of their commander, who had been mortally wounded. Steady advances brought the Union armies to Corinth, an important railroad centre, in June; and the Mississippi was opened up as far as Memphis by these successes of the armies and by the hard fighting of the gunboats at Island Number Ten and other places. At the northern boundary of the State of Mississippi the Union advance stopped for the time, but what had been gained was held.

New
Orleans.

282. At the same time the Mississippi was opened in part from below. A great naval expedition under Farragut and Porter, with a land force under Butler, sailing from Fort Monroe, came to the mouth of the Mississippi. Farragut ran past the forts above the mouth of the river, sank the ironclads which met him, and captured New Orleans (April 25). The land forces then took possession of it and the forts, while the fleet cleared the river of obstacles and Confederate vessels as far as Port Hudson and Vicksburgh, where the Confederate works were situated on bluffs too high for a naval attack.

The
"Mou-
tor" and
"Merri-
mac."

283. The energy of the combatants had already brought ironclad vessels to the test which they had not yet met elsewhere, that of actual combat. Western ingenuity had produced a simple and excellent type of river ironclad by cutting down river steamers and plating them with railroad or other iron. The type needed for the rougher Eastern waters was different, and the Confederates converted the frigate "Merrimac," captured at Norfolk, into an ironclad of a more sea-going type. The battle between her and the "Monitor" (March 8), in Hampton Roads, was indecisive; but the "Merrimac" was driven back to Norfolk, the blockade and the cities of the Atlantic coast, which had seemed to be at its mercy, were saved, and the day of wooden war-vessels was seen to be over. Before the end of the following year there were 75 ironclads in the United States navy; the number of vessels had increased to 588, with 4443 guns and 35,000 men.

The pen-
insular
cam-
paign.

284. The hundred miles between Washington and Richmond are crossed by numberless streams, flowing south-east, and offering strong defensive positions, of which the Confederates had taken advantage. M'Clellan (§ 271) therefore wished to move his army to Fort Monroe and attack Richmond from that point, on the ground of Cornwallis's campaign of 1781. He believed that such a movement would force the Confederate armies away from Washington to meet him. The administration, believing that such a movement would only open the way for the enemy to capture Washington—a more valuable prize than Richmond—gave directions that a part of M'Clellan's force, under M'Dowell, should take the overland route as far as Fredericksburgh, while the rest, under M'Clellan, were moving up the peninsula towards Richmond; and that, as the enemy withdrew to meet the latter, a junction of the two divisions should take place, so as to carry out M'Clellan's plans without uncovering Washington. But a month was spent in besieging Yorktown; when the attempt was made to form the junction with M'Dowell it involved the separation of the two wings by the little river Chickahominy; and in May the spring rains turned the little stream into a wide river, and the army was divided. Joseph E. Johnston, the Confederate commander, at once attacked the weaker wing at Seven Pines and Fair Oaks, but was beaten, and was himself wounded and compelled to leave the service for a time. This event gave his place to Robert E. Lee, whose only military service in the war up to this time had been a failure in western Virginia. He was now to begin, in conjunction with Thomas J. ("Stonewall") Jackson, a series of brilliant campaigns.

Seven
Pines
and Fair
Oaks.

Jack-
son's
raid.

285. From Staunton, 100 miles west of Richmond, the Shenandoah valley extends north-east to the Potomac, whence there is an easy march of 75 miles south-east to Washington. Jackson struck the Union forces in the valley, drove them to the Potomac, and excited such alarm in Washington that M'Dowell's troops were hastily withdrawn from Fredericksburgh. Having thus spoiled M'Clellan's plan of junction, and taken some 40,000 men from him, Jackson hurried to Richmond. Lee met him on the north side of the Chickahominy, and the two armies

attacked M'Clellan's right wing at Gaines's Mill, and cut the connexion between it and its base of supplies on the York river (June 26). Unable to reunite his wings and regain his base, M'Clellan was forced to draw his right wing south, and attempt to establish another base on the James river. Lee and Jackson followed hard on his retreat, and the "seven days' battles" were the most desperate of the war up to this time, the principal battles being those of Savage's Station (June 29), Glendale (June 30), and Malvern Hill (July 1). The last ended the series, for M'Clellan had reached the James, and his army had fixed itself in a position from which it could not be driven.

The
"seven
days'
battles."

286. Pope had succeeded M'Dowell, and Jackson at-
tacked and beat him on the battle ground of Bull Run (August 29), driving his army towards Washington. M'Clellan was at once recalled to defend the capital. As he withdrew from the peninsula, Lee joined Jackson, and the whole Confederate army, passing to the north-west of Washington, began the first invasion of the North. As it passed through the mountains of north-western Maryland, the army of the Potomac, which had been brought up through Maryland in pursuit, reached its rear, and forced it to turn and fight the battle of Antietam, or Sharps-
Antietam.
burgh, September 17. Both sides claimed the victory, but Lee was compelled to recross the Potomac to his former position. M'Clellan was blamed for the slowness of his pursuit and was removed, Burnside (p. 788) becoming his successor. The only great event of his term of command was his attempt to storm the heights behind Fredericksburgh (December 13) and the terrible slaughter of his defeat. Hooker was then put in his place. The year 1862 thus closed with the opposing armies in about the same positions as at the beginning of the war.

287. At the beginning of the war the people and leaders of the North had not desired to interfere with slavery, but circumstances had been too strong for them. Lincoln had declared that he meant to save the Union as he best could,—by preserving slavery, by destroying it, or by destroying part and preserving part of it. Just after the battle of Antietam he issued his proclamation calling on the revolted States to return to their allegiance before the following January 1, otherwise their slaves would be declared free men. No State returned, and the threatened declaration was issued January 1, 1863. As president Lincoln could issue no such declaration; as commander-in-chief of the armies and navies of the United States he could issue directions only as to the territory within his lines; but the Emancipation Proclamation applied only to territory outside of his lines. It has therefore been debated whether the proclamation was in reality of any force. It may fairly be taken as an announcement of the policy which was to guide the army, and as a declaration of freedom taking effect as the lines advanced. At all events, this was its exact effect. Its international importance was far greater. The locking up of the world's source of cotton-supply had been a general calamity, and the Confederate Government and people had steadily expected that the English and French Governments, or at least one of them, would intervene in the war for the purpose of raising the blockade and releasing the Southern cotton. The conversion of the struggle into a crusade against slavery made intervention impossible for Governments whose peoples had now a controlling influence on their policy and intelligence enough to understand the issue which had now been made.

The
Emanci-
pation
Procla-
mation.

288. Confederate agents in England were numerous and active. Taking advantage of every loophole in the British Foreign Enlistment Act, they built and sent to sea the "Alabama" and "Florida," which for a time almost drove American commerce from the ocean. Whenever they were

Confede-
rate
privat-
eers.

closely pursued by United States vessels they took refuge in neutral ports until a safe opportunity occurred to put to sea again. Another, the "Georgia," was added in 1863. All three were destroyed in 1864,—the "Florida" by a violation of Brazilian neutrality, the "Georgia" after an attempt to transfer her to neutral owners, and the "Alabama" after a brief sea-fight with the "Kearsarge," off Cherbourg (June 19). Confederate attempts to have iron-clads equipped in England and France were unsuccessful.

289. In the west (§ 281) Bragg (p. 788), now in command of the Confederate forces, turned the right of the Union line in southern Tennessee, and began an invasion of Kentucky about the time when Lee was beginning his invasion of the North. Carrying off much booty, he retired into Tennessee. Towards the end of the year Rosecrans moved forward from Nashville to attack him. The armies met at Murfreesboro', and fought a drawn battle during the last day of the year 1862 and the first two days of January 1863. The western armies were now in four parts,—that of Rosecrans near Murfreesboro', that of Grant near Corinth, that of Schofield in Missouri and Arkansas, and that of Banks in Louisiana. The complete opening of the Mississippi being the great object, the burden of the work fell to Grant, who was nearest the river. Vicksburgh was the objective point, and Grant at first attempted to take it from the opposite or western bank of the river. Failing here, he moved south to a favourable point for crossing, and used the river fleet to transfer his army to the eastern bank. He was now on the Vicksburgh side of the river. J. E. Johnston was north-east of him, at Jackson, with a weaker army; the bulk of the Confederate forces was at or near Vicksburgh, under Pemberton. Johnston wanted no siege of Vicksburgh; Pemberton wanted no junction with Johnston, which might cost him the glory of defeating Grant; and Grant solved their difficulty for them. Moving north-east he struck Johnston's army near Jackson, beat it, and drove it out of any possibility of junction. He then turned westward, fighting several sharp battles as he went, and late in May he had Pemberton shut up in Vicksburgh. His lines were maintained for six weeks, and then (July 4, 1863) the finest Confederate army in the west surrendered. Port Hudson surrendered to Banks five days later: the Mississippi was opened from end to end, and the Confederacy was cleft in twain. From this time communication between the two parts of the Confederate States became increasingly more difficult, and the transfer of supplies from the rich country west of the Mississippi was almost at an end. There was little further fighting to the west of the great river, except an intermittent guerilla warfare and the defeat of Banks's expedition against north-western Louisiana early in 1864. When the war ceased in the east, the isolated western half of the Confederacy fell with it.

290. While Grant was besieging Vicksburgh, Rosecrans had begun to move from the eastern end of the Union line in Tennessee against Bragg at Chattanooga. He drove Bragg through the place, and a dozen miles beyond it, into Georgia. Here the Confederate army took position behind Chickamauga creek, and inflicted a complete defeat upon the pursuing Union forces (September 19–20, 1863). Thomas covered the rear stubbornly, and secured a safe retreat into Chattanooga, but the possession of the mountains around the place enabled Bragg to cut off almost all roads of further retreat and establish a siege of Chattanooga. Bragg was so confident of success that he detached a part of his army, under Longstreet, to besiege Knoxville, in eastern Tennessee. Grant was ordered to take command at Chattanooga, and went thither, taking Sherman and others of the officers who

had taken part in his Vicksburgh campaign. He soon opened new routes of communication to the rear, supplied and reinforced his army, and began to prepare for the storming of the mountains before him. His assaults on Lookout Mountain and Missionary Ridge (November 23–25) were among the most dramatic and successful of the war. Bragg was driven out of all his positions and back to Dalton, where Davis was compelled by the complaints of his people to remove him, and appoint J. E. Johnston his successor. Longstreet broke up the siege of Knoxville, and made good his retreat across the mountains into Virginia to join Lee.

291. The army of the Potomac, under Hooker, kept its place near Fredericksburgh (§ 286) until May 1863. Hooker then began a movement across the Rapidan towards Richmond, and was defeated in the battle of Chancellorsville (May 2–3). The victorious army suffered the severest of losses in the death of Jackson, but this did not check Lee's preparations for a second invasion of the North, which began the next month. As his army moved northwards, very nearly on the route which it had followed the year before, the army of the Potomac held a parallel course through Maryland and into Pennsylvania. The Confederate forces penetrated farther than in 1862; their advance came almost to Harrisburgh, and threw the neighbouring Northern cities into great alarm; but the pursuing army, now under Meade (p. 790), met Lee at Gettysburgh (July 1–3) and defeated him. The Confederate army, assaulting its enemy in very strong positions, suffered losses which were almost irreparable, and it was never again quite the same army as before Gettysburgh. Some Northern critics were inclined to think that Lee's former successes had really been due to Jackson's genius, and that he had lost his power in losing Jackson. The campaign of 1864 was to prove the contrary. The customary retreat brought the two armies back to very nearly the same positions which they had occupied at the beginning of the war, the Rappahannock flowing between them. Here they remained until the following spring.

292. The turning-point of the war was evidently in the early days of July 1863, when the victories of Vicksburgh and Gettysburgh came together. The national Government had at the beginning cut the Confederate States down to a much smaller area than might well have been expected; its armies had pushed the besieging lines far into the hostile territory, and had held the ground which they had gained; and the war itself had developed a class of generals who cared less for the conquest of territory than for attacking and destroying the opposing armies. The great drafts on the future which the credit of the Federal Government enabled the North to make gave it also a startling appearance of prosperity; so far from feeling the war, it was driving production of every kind to a higher pitch than ever before. The cities began to show greater evidences of wealth, and new rich men appeared, many of them being the "shoddy aristocracy," who had acquired wealth by mis-serving the Government, but more being able men who had grasped the sudden opportunities offered by the changes of affairs.

293. The war had not merely developed improved weapons and munitions of war; it had also spurred the people on to a more careful attention to the welfare of the soldiers, the fighting men drawn from their own number. The Sanitary Commission, the Christian Commission, and other voluntary associations for the physical and moral care of soldiers received and disbursed very large sums. The national Government was paying an average amount of \$2,000,000 per day for the prosecution of the war, and, in spite of the severest taxation, the debt grew to \$500,000,000 in June 1862, to twice that amount a year

The current of success changes.

later, to \$1,700,000,000 in June 1864, and reached its maximum August 31, 1865,—\$2,845,907,626. But this lavish expenditure was directed with energy and judgment. The blockading fleets were kept in perfect order and with every condition of success. The railroad and telegraph were brought into systematic use for the first time in modern warfare. Late in 1863 Stanton, the secretary of war, moved two corps of 23,000 men from Washington to Chattanooga, 1200 miles, in seven days. A year later he moved another corps, 15,000 strong, from Tennessee to Washington in eleven days, and within a month had collected vessels and transferred it to North Carolina. Towards the end of the war, when the capacity of the railroad for war purposes had been fully learned, these sudden transfers of troops by the Federal Government almost neutralized the Confederate advantage of interior lines.

Conscription.

294. On the other hand, the Federal armies now held almost all the great Southern through lines of railroad, except the Georgia lines and those which supplied Lee from the South (§ 296). The want of the Southern people was merely growing in degree, not in kind. The conscription, sweeping from the first, had become omnivorous; towards the end of the war every man between seventeen and fifty-five was legally liable to service, and in practice the only limit was physical incapacity. In 1863 the Federal Government also was driven to conscription. The first attempts to carry it out resulted in forcible resistance in several places, the worst being the "draft riots" in New York (July), when the city was in the hands of the mob for several days. All the resistance was put down; but exemptions and substitute purchases were so freely permitted that the draft in the North had little effect except as a stimulus to the States in filling their quotas of volunteers by voting bounties.

Grant and Sherman.

295. Early in 1864 Grant (§ 290) was made lieutenant-general, with the command of all the armies. He went to Washington to meet Lee, leaving Sherman to face Johnston at Dalton. Events had thus brought the two ablest of the Confederate generals opposite the two men who were the best product of the war on the Northern side. It remained to be seen whether Lee, with his army of northern Virginia, could resist the methods by which Grant and Sherman had won almost all the great tableland which occupies the heart of the country east of the Mississippi. And it remained to be seen, also, whether the reputation which Grant had won at a distance from the political atmosphere of Washington would not wither in his new position. It was necessary for him to take the overland route to Richmond, or meet M'Clellan's fate. He did not hesitate. Early in May 1864, with about twice as many men (125,000) as Lee, he entered the "Wilderness" on the other side of the Rapidan. At the same time he sent 30,000 men, under Butler, up the James river; but this part of his plan proved of comparatively little service.

"Wilderness" campaign.

296. Two weeks' hard fighting in the Wilderness and at Spotsylvania Court House (May 5-18), and four days more at North Anna (May 23-27), with flank movements as a means of forcing Lee out of positions too strong to be taken from the front, brought the army of the Potomac to Cold Harbor, in the immediate defences of Richmond. One assault, bloodily repulsed, showed that there was no thoroughfare in this direction. Lee had so diligently prepared that his position became stronger as he was driven into greater concentration; and Grant began to move along the eastern face of the line of Confederate fortifications, striking at them as he passed them, but finding no weak spot. As he crossed the James river and reached Petersburg, he came at last into dangerous

proximity to the railroads which brought Lee's supplies from the South—the Weldon Railroad, running directly south, the Danville Railroad, running south-west, and the Southside Railroad, running west. At this end of his line, therefore, Lee kept the best part of his troops, and resisted with increasing stubbornness Grant's efforts to carry his lines farther to the south-west or to reach the railroads. Resorting to the plan which had been so effective with M'Clellan, he sent Early on a raid up the Shenandoah Valley, to threaten Washington (July). But Early was not Jackson, and he returned with no more success than the frightening of the authorities at Washington. Grant put Sheridan in command in the valley, and he beat Early at Cedar Creek (October), scattering his army for the remainder of the war. In August Grant succeeded in seizing a few miles of the Weldon Railroad; but Lee brought his supplies in waggons round that portion held by Grant. Late in the year this was stopped by the destruction of some twenty miles of the road. Here Grant was himself stopped for the time. Lee had so taken advantage of every defensive position that Grant could not reach the nearer of the other two railroads without an advance of 15 miles, or the further one without a circuit of about 40 miles. The two armies remained locked until the following spring. Grant, however, was operating still more successfully elsewhere through Sherman.

297. Sherman (§ 295) had moved on the same day as Grant (May 5). Johnston's retreat was skilfully conducted; every position was held to the last moment; and it was not until the middle of July that Sherman had forced him back to his strongest lines of defence—those around Atlanta. The Confederate forces could not retreat much beyond Atlanta, for the great central tableland here begins to fall into the plains which stretch to the Atlantic. Sherman had now been brought so far from his base that the two armies were much more nearly on an equality than in May; and Johnston was preparing for the decisive battle when Davis made Sherman's way clear. A feature in Davis's conduct of the war had been his extraordinary tendency to favouritism. He had been forced to take Johnston as commander in Georgia; and the widespread alarm caused by Johnston's inexplicable persistence in retreating gave him the excuse he desired. He removed Johnston (July 17), naming Hood (p. 789), a "fighting general," as his successor. Before the end of the month Hood had made three furious attacks on Sherman and been beaten in all of them. Moving around Atlanta, as Grant was doing around Petersburg, Sherman cut the supplying railroads, and at last was able to telegraph to Washington (September 2), "Atlanta is ours, and fairly won."

Atlanta.

298. Hood, by the direct command of Davis, then adopted a course which led to the downfall of the Confederacy in the following spring. Moving from between Sherman and the open country, he set out for Tennessee, expecting to draw Sherman after him. Sherman sent Thomas (p. 790) to Nashville, called out the resources of the North-West to support him, and left Hood to his march and his fate. Hood reached Nashville; but in the middle of December Thomas burst out upon him, routed his army, and pursued it so vigorously that it never again reunited. One of the two great armies of the Confederacy had disappeared; and Sherman, with one of the finest armies of the war, an army of 60,000 picked veteran troops, stood on the edge of the Georgia mountains, without an organized force between him and the back of Lee's army in Virginia.

299. In the meantime the presidential election of 1864 had taken place, resulting in the re-election of Lincoln, of 1864.

Petersburgh.

Johnston's retreat.

with Andrew Johnson as vice-president. The Democratic convention had declared that, after four years of failure to restore the Union by war, during which the constitution had been violated in all its parts under the plea of military necessity, a cessation of hostilities ought to be obtained, and had nominated McClellan (p. 789) and Pendleton. Farragut's victory in Mobile Bay (August 5), by which he sealed up the last port, except Wilmington, of the blockade-runners, and the evidently staggering condition of the Confederate resistance in the east and the west, were the sharpest commentaries on the Democratic platform; and its candidates carried only three of the twenty-five States which took part in the election. The thirty-sixth State—Nevada—had been admitted in 1864.

Admission of Nevada.

Sherman's march through Georgia and the Carolinas.

300. Sherman began (November 16, 1864) the execution of his own plan,—to “send back his wounded, make a wreck of the railroad, and, with his effective army, move through Georgia, smashing things to the sea.” He had been drawing supplies from a point 500 miles distant, over a single railroad. He now destroyed the railroad and the telegraph, cut off his communication with the North, and moved towards the Atlantic coast. The sea was reached on December 12, and Savannah was taken on the 20th. He had threatened so many points, and kept the enemy in so much doubt as to his objects, that there had hardly been men enough in his front at any one time to make a skirmish line. On January 15, 1865, the army moved north from Savannah, through Columbia, to Fayetteville, N.C. The march had forced the evacuation of Charleston and the other coast cities, and their garrisons had been put by Davis under command of Johnston as a last hope. Wilmington, which had been captured by a land and sea force on the day when Sherman left Savannah, was an opening for communication with Washington; and it would have been possible for Sherman, with Wilmington as a base, to crush Johnston at once. All that he cared to do was to hold Johnston where he was while Grant should begin his final attack on Lee.

301. During the opening days of March 1865 Sheridan, with a body of cavalry, moved from the Shenandoah Valley along the James river to a junction with Grant (§ 296). On the way he had ruined the canal and railroad communication directly west from Richmond, and had reduced Lee to dependence on the two railroads running south-west. Grant resumed his attempts to work his lines farther round to the south of Petersburg; and, with each successful advance, Lee was compelled to lengthen his thin line of men. Sheridan was put in command on the extreme left; he pushed forward to Five Forks, destroyed the Southside Railroad (April 1), and held his ground. Giving Lee time to lengthen his line to meet this new danger, Grant gave the signal for a general advance the next day. It was successful everywhere; Petersburg was taken, and Richmond the next day; Davis and the other political leaders fled to North Carolina; and Lee retreated westward, hoping to join Johnston. The pursuit was too hot, and he surrendered (April 9). All the terms of surrender named by Grant were generous: no private property was to be surrendered; the men were even to retain their horses, “because they would need them for the spring ploughing and farm-work”; and both officers and men were to be dismissed on parole, not to be disturbed by the United States Government so long as they preserved their parole and did not violate the laws. It should be stated, also, to Grant's honour that, when the politicians afterwards undertook to repudiate some of the terms of surrender, he personally intervened and used the power of his own name to force an exact fulfilment. Johnston surrendered on much the

Five Forks.

Surrender of Lee.

same terms (April 26), after an unsuccessful effort at a broader settlement. All organized resistance had now ceased; Union cavalry were ranging the South, picking up Government property or arresting leaders; but it was not until May that the last detached parties of Confederates, particularly beyond the Mississippi, gave up the contest.

302. Just after Lee's surrender President Lincoln died by assassination (April 15), the theatrical crime of a half-crazed enthusiast. Even this event did not impel the American people to any vindictive use of their success for the punishment of individuals. In the heat of the war, in 1862, Congress had so changed the criminal law that the punishment of treason and rebellion should no longer be death alone, but death or fine and imprisonment. Even this modified punishment was not inflicted. There was no hanging for treason; some of the leaders were imprisoned for a time, but were never brought to trial. The leader and president of the Confederate States is living (1887) quietly at his home in Mississippi; and the vice-president, before his death, had returned to the Congress of the United States as an efficient and respected member.

303. The armies of the Confederacy are supposed to have been at their strongest (700,000) at the beginning of 1863; and it is doubtful whether they contained 200,000 men in March 1865. The dissatisfaction of the Southern people at the manner in which Davis had managed the war seems to have been profound; and it was only converted into hero-worship by the ill-advised action of the Federal Government in arresting and imprisoning him. Desertion had become so common in 1864, and the attempts of the Confederate Government to force the people into the ranks had become so arbitrary, that the bottom of the Confederacy, the democratic elements which had given it all the success it had ever obtained, had dropped out of it before Sherman moved northward from Savannah; in some parts the people had really taken up arms against the conscripting officers. On the contrary, the numbers of the Federal armies increased steadily until March 1865, when they were a few hundreds over a million. As soon as organized resistance ceased, the disbanding of the men began; they were sent home at the rate of about 300,000 a month, about 50,000 being retained in service as a standing army. The debt reached its maximum August 31, 1865, amounting to \$2,845,907,626.56. Some \$800,000,000 of revenue had also been spent mainly on the war; States, cities, counties, and towns had spent their own taxation and accumulated their own debts for war purposes; the payments for pensions will probably amount to \$1,500,000,000 in the end; the expenses of the Confederacy can never be known; the property destroyed by the Federal armies and by Confederate armies can hardly be estimated; and the money value (\$2,000,000,000) of the slaves in the South was wiped out by the war. Altogether, while the cost of the war cannot be exactly calculated, \$8,000,000,000 is a moderate estimate.

304. In return for such an expenditure, and the death of probably 300,000 men on each side, the abiding gain was incalculable. The rich section, which had been kept back in the general development by a single institution, and had been a clog on the advance of the whole country, had been dragged up to a level with the rest of the country. Free labour was soon to show itself far superior to slave labour in the South; and the South was to reap the largest material gain from the destruction of the Civil War (§ 314). The persistent policy of paying the debt immediately resulted in the higher taxation falling on the richer North and West; and the new wealth of the South will for ever escape the severe taxation which the other sections have been compelled to feel. As a result of the struggle the moral stigma of slavery was removed. The

power of the nation, never before asserted openly, had made a place for itself; and yet the continuing power of the States saved the national power from a development into centralized tyranny. And the new power of the nation, guaranteeing the restriction of government to a single nation in central North America, gave security against any introduction of international relations, international armament, international wars, and continual war taxation into the territory occupied by the United States. An approach for four years to the international policy of Europe had given security against its future necessity. Finally, democracy in America had certainly shown its ability to maintain the unity of its empire.

XI. THE RECONSTRUCTED NATION: 1865-87.

The 13th
amend-
ment.

305. The Federal Government had begun the war with an honest expression of its determination not to interfere with slavery; the progress of the war had forced it into passing the 13th amendment in 1865, abolishing slavery in the United States for ever. In much the same way circumstances were driving it into interference with what had always been regarded as the rights of the States. In the latter case the process was certain to find an obstacle in Lincoln's successor, Johnson. He had been elected, like Tyler, to the comparatively unimportant office of vice-president in order to gain the votes of War Democrats; and now the dominant party found itself with a president opposed to its fundamental views of the powers of the Federal Government. The case was worse for Johnson, since the war had built up a new party. Until 1861 the Republican party had been a mixture of a strong Whig element and a weak Democratic element; now it was a real party, and demanded complete loyalty from its leaders, not skilful compromises between its two elements. Just as in the cases of Seward, Sumner, Trumbull, and very many of its original leaders, the party was now ready to repudiate its leaders if they did not come up to its ideas.

President
Johnson
and the
Re-
publican
party.

Presi-
dential
recon-
struction.

306. The universal idea in 1861 had been that the States were to be forced to return with all their rights unimpaired. This original notion was seriously limited by the Emancipation Proclamation of 1862-63; as soon as the president opened a door, by demanding a recognition of the abolition of slavery as a condition precedent to the return of a State, the way was just as open for the imposition of whatever conditions Congress as well should think essential to an abiding peace. But Congress was not called on to face the difficulty for some time. President Lincoln went on to reorganize civil government in Virginia, Tennessee, Arkansas, and Louisiana, by giving amnesty to such voters as would swear to support the Government of the United States and the abolition of slavery, and recognizing the State officers elected by such voters. When Johnson succeeded to the presidency in April 1865 he had a clear field before him, for Congress was not to meet until December. Before that time he had reorganized the governments of the seceding States; they had passed the 13th amendment (§ 125); and they were ready to apply for readmission to Congress. Tennessee was readmitted in 1866 by Congress; but the other seceding States were refused recognition for a time.

307. It was not possible that slave-owners should pass at one step from the position of absolute masters to that of political equality with their late slaves. Their State legislation assumed at once a very paternal character. Every means was taken, in the passage of contract and vagrant laws, and enactments of that nature, to force the freedmen to work; and the legislation seemed to the Northern people a re-establishment of slavery under a new name. Johnson had a very unhappy disposition for such a state of affairs; he had strong convictions, great

stubbornness, and a hasty, almost reckless, habit of speech. As soon as it became clear that Congress did not intend to readmit the Southern States at once he began (February 1866) to denounce Congress in public speeches as "no Congress" so long as it consisted of representatives from but part of the States. The quarrel grew rapidly more bitter; the Congressional elections of 1866 made it certain that the Republicans would have a two-thirds majority in both houses through the rest of Johnson's term of office; and the majority passed over the veto (§ 113) every bill which Johnson vetoed. Thus were passed the Freedmen's Bureau Bill (1866) for the protection of the emancipated negroes, the Act for the admission of Nebraska, with equal suffrage for blacks and whites (1867), the Tenure of Office Bill, making the assent of the senate necessary to removals, which had always been regarded as within the absolute power of the president (1867), and the Reconstruction Acts (1867). The increasing bitterness of the quarrel between the president and the majority in Congress led to the impeachment of the president in 1868 for removing Stanton, the secretary of war, without the assent of the senate; but on trial by the senate a two-thirds majority for conviction could not be obtained, and Johnson served out his term.

Admis-
sion of
Nebraska.

Impeach-
ment of
the pre-
sident.

308. The Reconstruction Acts divided the seceding States into military districts, each under command of a general officer, who was to leave to the State Governments then in existence such powers as he should not consider to be used to deprive the negroes of their rights. The State Governments of the seceding States were to be considered provisional only, until conventions, elected without the exclusion of the negroes, but with the exclusion of the leading Confederates, should form new or "reconstructed" State Governments, on a basis of manhood suffrage, and their legislatures should ratify the 14th amendment to the constitution (§ 125). This amendment, passed by Congress in 1866, was in five sections, but had three main divisions. (1) All persons born or naturalized in the United States were declared citizens of the United States and of their States, and the States were forbidden to abridge the "privileges or immunities" of such citizens. This was to override the Dred Scott decision (§ 249). (2) The representation of the States in Congress was to be reduced in proportion to the number of persons whom they should exclude from the elective franchise. This was to induce the States to adopt negro suffrage. On the other hand, specified classes of Confederate office-holders were excluded from office until Congress should remove their disabilities. (3) The war debts of the Confederacy and the seceding States were declared void for ever, and the war debt of the United States was guaranteed. Congress was given power to enforce all these provisions by "appropriate legislation."

The 14th
amend-
ment.

309. The presidential election of 1868 sealed the process of reconstruction. The Democrats opposed it, and nominated Seymour (p. 790) and Blair; the Republicans endorsed it, and nominated Grant (p. 788) and Colfax (p. 788). Virginia, Mississippi, and Texas were the only States of the late Confederacy which were excluded from this election; all the rest had been reconstructed, and readmitted by Congress in June 1868; and the Republican candidates carried twenty-six of the thirty-four voting States, and were elected. The legislatures of the reconstructed States, representing mainly the negroes freed by the war, were devoted supporters of the new order of things; and their ratifications secured the necessary three-fourths of the States to make the 14th amendment a part of the constitution (1868). Congress went on to propose a 15th amendment, forbidding the United States, or any State, to limit or take away the right of suffrage by reason of race, colour, or previous condition of servitude. This was

Election
of 1868.

The 15th
amend-
ment.

ratified by the necessary number of States, and became a part of the constitution (1870). Ratification of it was imposed as an additional condition on Virginia, Mississippi, and Texas, which had rejected the original terms of readmission. They accepted it, and were readmitted (1870). It was not until January 30, 1871, that all the States were once more represented in Congress.

310. The foreign affairs of the United States during this period took on a new appearance. The country's promptness in disarming at the end of the war put it under no disadvantage in dealing with other nations; power and pacific intentions were united in the act. The successful completion of the Atlantic cable (1866) gave a celerity and directness to diplomacy which was well suited to American methods. The tone of American complaint at the continued presence of French soldiers in

Mexico. Mexico grew more emphatic as the success of the war became assured; and, at the end of the war, significant movements of troops to the Mexican frontier led the French emperor to withdraw his support of Maximilian.

Alaska. Alaska was purchased from Russia in 1867. The treaty of Washington (1871) provided for the settlement by arbitration of the "Alabama" disputes, of the north-western boundary, and of the claims of Canada for damages for use of the shore by American fishermen.

The "Virginian" case. The capture by a Spanish man-of-war of the "Virginian," a vessel claiming American nationality, and the execution of a part of her crew (1873), threatened to interrupt friendly relations with Spain; but the rupture was averted by proof that the vessel's papers were false. Chinese

The Chinese. immigration had grown largely on the Pacific coast. There were riotous attacks on the Chinese by worthless white men; and many others did not feel that they were a desirable political addition to the population of the United States. A treaty with China was obtained (1880), by which the limitation of Chinese immigration was allowed.

"Dynamiters." So, also, the raising of money in the United States to assist the destruction of private and public buildings in England by some of the more desperate of the Irish people (1885) gave England reason for discontent. But the American Government had no power in the premises. The matter was under the exclusive jurisdiction of the State Governments; and, as soon as these began to apply the common law to the case, the "dynamite subscriptions" disappeared. Further difficulties made their appearance as to the Canadian fisheries (1886-87). When American fishing-vessels bought ice or bait in Canadian ports, the Canadian Government seized and condemned them, on the ground that such purchases were acts "preparatory to fishing in Canadian waters." Retaliatory measures were suggested, but no full retaliatory system has been adopted, nor has the dispute yet been settled (1887).

Gold. 311. The prosperity of the United States knew no cessation. It had been found that gold was not confined to California. In 1858 it had been discovered in Colorado, at Pike's Peak. It has since been found in most of the Pacific States and Territories. Silver, a metal hardly known hitherto in the United States, was discovered in Nevada (1858); and this metal also has been found to be widely scattered over the Pacific coast. Petroleum was found in north-western Pennsylvania (1859), and the enormous drain of this oil from the earth still continues without apparently affecting the reservoir. The coal-fields of the country began to be understood clearly. Taylor, in 1848, thought that the coal-area of the United States amounted to 133,000 square miles; it was estimated in 1883 at over 200,000 square miles. Natural gas has since come into use, and has made production of many kinds cleaner, more effective, and cheaper. Manufactures and every variety of production have increased with cumulative

rapidity. In 1860 the largest flouring-mill in the United States was in Oswego, N.Y., the next two in Richmond, Va., and the fourth in New York city; and the capacity of the largest was only 300,000 barrels a year. In 1887 the flour production of Minneapolis, almost unknown in 1860, is 100,000 barrels a week or 5,000,000 barrels a year. The absolute free trade which prevails between the States has resulted in a constant shifting of centres of production, a natural arrival at the best conditions of production, and an increasing development. Mulhall, perhaps safer as a foreign authority, gives the total manufactures of the United States as £682,000,000 in 1870 and £888,000,000 in 1880, Great Britain coming next with £642,000,000 in 1870 and £758,000,000 in 1880. He estimates the accumulated wealth of Great Britain at Wealth. £8,310,000,000 in 1870 and £8,960,000,000 in 1880, an increase of £650,000,000, and that of the United States at £6,320,000,000 in 1870 and £7,880,000,000 in 1880, an increase of £1,560,000,000. If he had followed the American census returns his value for 1880 would have been 25 per cent. larger. In 1870 the United States stood third in wealth; in 1880 they had passed France in the race, and stood at least second. The country whose population has been developed within 280 years does already one-third of the world's mining, one-fourth of its manufacturing, and one-fifth of its agriculture; and at least one-sixth of the world's wealth is already concentrated in the strip of territory in central North America which is the home of the United States.

312. Of the 290,000 miles of railroad in the world, probably 135,000 are in the United States. Of the 600,000 miles of telegraph lines, more than a fourth are in the United States; and the American telephone lines are probably still longer in the aggregate. The new development of the American railways began in 1869, Railways. when Vanderbilt consolidated the Hudson River and New York Central Railroads and formed a trunk line to the west. It was undoubtedly hastened by the completion of the Central Pacific line in that year, and it has resulted in a universal tendency to consolidation of railways and the evolution of "systems," under combined managements (§ 273). The coincident introduction of Bessemer steel rails, the steady increase of weight carried by trains, and concentrated competition have reduced railway freight rates through the whole of this period. The average rates per ton per mile were 1·7 cents in New York in 1870 and 0·8 in 1880, 2·4 cents in Ohio in 1870 and 0·9 in 1880. The persistent effects of such a process on the industries of so large a country can hardly be described.

313. The extraordinary stimulus given to a new territory, if it has any basis for production, by the introduction of a new railway, is also quite beyond description. Most of the Western railways have had to build up their own traffic; the railway has been built, and the sales of lands have afterward brought into existence the towns and even States which are to support it. Nebraska was described in the Government reports of 1854 as a desert country, hopelessly unfitted for agriculture, and the maps of the time put it down as a part of the "Great American Desert." It is now one of the leading agricultural States of the Union, with a population of a million; and Dakota is waiting only for the legal form of admission to become a State. The profits of railway construction, the opportunities for skilful management in the development of territory, and the spice of gambling which permeated the whole were great temptations to Americans to embark in the business. The miles of railway constructed per annum, which had been from 1000 to 3000 (averaging about 1500 miles) for the period 1859-68, rose to 4615 miles in 1869, to 6070 miles in 1870, and to 7379 miles

in 1871. Masses of labourers were brought into situations from which they could not easily escape; and masses of capital were locked up in railways which were finally unproductive, and resulted only in total loss. The result was the financial crisis of 1873, from which the country has hardly yet fully recovered.

Financial
crisis of
1873.

Progress
of the
South.

314. For the first time in the history of the United States, the South has taken a normal part in all this development (§ 304), though it was not until about 1885 that Southern progress was fully understood by the rest of the country. Staggering under a load of poverty and discouragement which might have appalled any people, with the addition of social problems which no other country has solved with any great satisfaction, the Southern people began to feel for the first time the healthy atmosphere of free labour. The former slave is a free labourer, and the white man has gone to work; white labour produced 10 per cent. of the cotton crop of 1860 and 55 per cent. of that of 1886. The last eighteen slave-labour crops of cotton amounted to 51,000,000 bales; the first eighteen free-labour crops amounted to 75,000,000 bales. And the latter figures are deceptive from the fact that, in their period, the South had turned a large percentage of its labour and capital into industries which had not been possible, only longed for, under the slave system. Cotton-seeds were waste under slavery: 600,000 tons of them were crushed in 1886, giving an entirely new production of \$12,000,000 per annum of cotton-seed oil. Southern railways, which had made but a meagre comparison with those of the North and West in 1860, began to assume something of the network appearance of the latter; they too began to concentrate into "systems," to reduce rates and improve service, and to develop new territory. Southern manufactures began to affect Northern markets; cotton-mills in the South began to reap the advantages of their immediate contiguity to their raw material. Pennsylvania ironmasters were startled as their product was undersold in the Philadelphia markets by Southern iron; and the great mineral fields of Tennessee and northern Georgia, Alabama, and Mississippi, over which Sherman's and Hood's men had so lately been tramping and fighting, were brought into notice and development. Wonderful as the general progress of the United States has been during this period, the share of the new South under free labour has been one of the most remarkable phases in it.

Increase
of popu-
lation.

315. The population rose from 31,443,321 in 1860 to 38,558,371 in 1870 and 50,155,783 in 1880. At the normal rate of increase up to 1860—one-third for each ten years—the increase from 1860 to 1870 should have been about ten and a half millions, instead of seven millions. The difference represents the physical influences of the civil war. This influence was shown most plainly in the Southern States, notably in South Carolina and Alabama, which had hardly any increase, and a real decrease in adult males. It should also be noticed that natural checks on the increase of population are plainly perceptible in the Atlantic States in 1880, and were probably in operation, to a less extent, in 1860-70, though they were made indistinguishable by the war. The increase in 1870-80 at the former normal rate should have been a little over a million more than it was. The tendency will be more evident in future, but it ought to be allowed for in 1860-70.

The era
of specu-
lation
and cor-
ruption.

316. The material prosperity of the country brought its own disadvantages. The sudden development of wealth gave the country for the first time a distinct wealthy class, not engaged in production of any kind, and very often having none of the characteristics of the people who are the real strength of the country. The inevitable

extravagance of Government management, aggravated by a period of civil war, when the people were disposed to excuse almost any error of detail for which good motives could be shown, had its reflex influence on the people, as well as on the Governments of the nation, the States, and the cities. An era of legal tender paper currency (§ 272), legally unvarying in value, but showing its effects in the constant shiftings of price in every other thing, brought uncertainty as to every article, price, and transaction. The people had learned that "unhappy lesson—that there is an easier way to make a dollar than by working for it"; and it was not long before speculation among the people called out its correlative of dishonesty among Government officials. Money was lavished on the navy; in expenditures on that branch of the service the United States stood third or fourth among the nations, while the effective results were discouraging. "Rings" of politicians obtained control of the larger cities. The "Tweed ring" in New York city was overthrown in 1872; but New York was not the only city of corruption: Philadelphia, Chicago, and almost every city large enough to have fat opportunities for fraud and to deprive universal suffrage of the general acquaintance of neighbours, each fell under control of its "ring," and was plundered without mercy. Corruption even attacked the judiciary; for the first time American judges were found who were willing to prostitute their positions, and the members of the "Erie ring" were able to hold their ill-gotten railroads because they owned the necessary judges. A "whisky ring" of distillers and Government employees (1874) assumed national proportions, and robbed the Government of a large percentage of its internal taxation on spirits. The "star-routes," in which the contracts for mail transportation were altered at the discretion of the contractor and the Government after the competition for the contracts had been decided, gave rise to as great scandals through the connivance of Government agents with dishonest contractors. No one who lived in this period will wonder at the pessimistic tone of the public speeches which marked the hundredth year of the republic (1876).

317. The republic had life and vigour in it, and its people showed no disposition to despair before the mass of corruption which confronted them. The newspapers attacked the star-route contractors, and drove the Government into an attack upon the ring, which broke it up. The efforts of private individuals, backed by newspapers, broke up the Tweed ring, banished or imprisoned its members, expelled the corrupt judges from the bench, and carried destruction into the widespread whisky ring. Local rings were attacked in city after city, were broken up and revived again, but always found the struggle for existence more and more desperate. The people have shown themselves almost vindictive in driving out of public life any who have been proved dishonest: when the "Credit Mobilier," the construction company of the Central Pacific Railroad, was shown to have bribed or influenced members of Congress to vote for it, there is ground for believing that the punishment was distributed more widely than justice demanded; and it has come to be recognized as a decided disadvantage for a public man to be known as shrewd rather than honest.

318. The completion of reconstruction in 1870, and the adoption of the 15th amendment (§ 125), made negro suffrage the law of the land, even in the Southern States. The Southern whites were the tax-payers; the negroes were the majority; and the negro legislatures proved hopelessly corrupt. In one or two States the whites recovered control of their States by hiring their negroes to remain at home on election day, or by threatening them with discharge for voting. Failing in this line of action

"Rings."

"Star-routes."

"Credit Mobilier."

The re-constructed Govern-ment.

"Ku-
Klux-
Klan."

in other States, the whites fell into a steady tendency towards violence. A widespread secret society, the "Ku-Klux-Klan," beginning with the effort to overawe the negro population by whipping and arson, was rapidly driven into political murders. The reconstructed Governments resisted as best they could. They tried to use the force of the State against the offenders; but the best part of the force of the State was the white element, which was most deeply involved in the resistance to the legal Government. On the application of the legislature of a State, or of the governor if the legislature cannot be summoned, the president may send Federal troops to suppress rebellion (§ 125). The reconstructed Governments called on President Grant for such aid, and received it. But the whites were the stronger race, struggling for property, and knowing well the letter of the law. They refused to resist the smallest atom of Federal authority: a large force of them, mainly old Confederates and excellent fighting men, who had seized the city of New Orleans and overturned the reconstructed Government (1874), retired quietly before a detachment of United States troops, and allowed the State Government to be restored. The little United States army in the South was kept busy. Wherever it appeared, resistance ceased at once, breaking out at the same time elsewhere. The whites had to gain but a single victory; as soon as they secured a majority in a State legislature they so arranged the election laws and machinery that a negro majority was thenceforth impossible. The legislatures and governors, with nearly all the local officers, were then Democrats; calls for Federal troops ceased at once; and the Republicans of the North, the dominant party of the nation, were reduced to the necessity of seeing their Southern vote disappear, without the ability to do anything to check the process. As the election of 1876 drew near, the reconstructed Governments of all the seceding States, except Florida, South Carolina, and Louisiana, had become Democratic.

Civil
Rights
Act.

Election
Act.

Force
Act.

319. Congress, which was controlled by the Republicans, had not been idle. The Civil Rights Act (1870) provided that fines and damages should be imposed for any attempt to violate or evade the 15th amendment or for conspiracy to deprive the negroes of the right of suffrage. The Election Act (1870) exercised for the first time the right to alter or amend State laws as to Federal elections which the constitution had given to Congress. This was strengthened by another Act in the following year. The Force Act (1871) went farther than the instincts of the American people could follow Congress. It provided that any conspiracy or combination strong enough to deprive the negroes of the benefits of the 14th amendment should be evidence of a "denial by the State of the equal protection of the laws" to all its citizens; that the president should be empowered to use the army, navy, and militia to suppress such combinations; that, when any combination should appear in arms, the act should be a rebellion against the United States; and that, in such case, the president should have power to suspend the writ of *habeas corpus* in the rebellious territory (§ 305).

320. It was plain that the Southern whites meant to govern their States with little present regard to the last two amendments, and that it was impossible to defeat their purpose without cutting up the State system in the South by the roots. Even in 1872 a strong element of the Republican party thought that the party policy had gone too near the latter course. It held a convention of its own, under the name of the Liberal Republican party, and nominated Greeley and Brown. The Democratic party, anxious to save local government and State rights in the South, but completely discredited by its opposition to the war, accepted the Liberal Republican platform and

Liberal
Re-
publican
party.

nominations. Its action was in one sense a failure; Greeley had been one of the bitterest and angriest critics of the Democratic party, and so many of the Democrats refused to vote for him that his defeat was hardly ever doubtful. The Republicans renominated Grant, with Henry Wilson for vice-president; and they received the votes of 286 of the 349 electors, and were elected. The action of the Democratic party in adopting the Liberal Republican platform, and thus tacitly abandoning its opposition to reconstruction, brought it back into the lines of political conflict and made it a viable party.

321. The election of 1876 was the first really contested election since 1860. The Democrats nominated Tilden and Hendricks (p. 789) and the Republicans Hayes and Wheeler (p. 790). The platforms showed no distinct grounds of party struggle, except that of the ins and the outs. The election turned on the votes of the Southern States in which the reconstructed Governments still held their own or claimed to do so; and the extra-constitutional device of an electoral commission resulted in a decision in favour of Hayes and Wheeler. As a part of the result, some arrangement had been made for the settlement of the Southern difficulties, for Grant immediately withdrew the troops from Florida, South Carolina, and Louisiana, and the reconstructed Governments of those States surrendered without a struggle. All the Southern States were now Democratic; the negroes had every right but that of voting; and even this was permitted to a sufficient extent to throw a veil over the well-understood general state of affairs. Colorado, the thirty-eighth State (and the last, Admission up to 1887), was admitted in 1876 and took part in this election of Colorado.

322. The Hayes administration was a welcome period of calm. The main subject of public interest was monetary, and much of it was due to the change of conditions during and since the war. In order to sell bonds during the war it had been necessary, not only to make the interest very high (in some cases 7·3 per cent.), but to sell them for the Government's own depreciated paper. The Act of 1869, to restore the public credit, pledged the faith of the United States that the bonds should be paid in coin. This had seemed very inequitable to some, but was acquiesced in. When the price of silver had fallen, in July 1876, to 47d., a ratio for gold and silver of 20:1, and it was found that an Act of 1873 had dropped the silver dollar from the coinage, the people jumped to the conclusion that this was a trick of the bondholders to secure a further advantage in the payment of their bonds in the more valuable metal only. It was useless to urge that for forty years before 1873 the silver dollar had been token money, and that its average coinage had been only about \$150,000 a year; the current was too strong to be resisted, and Congress passed (1878) an Act to restore the silver dollar to the coinage, to compel the coinage of at least \$2,000,000 in silver per month, and to make the silver dollar legal tender to any amount. The Act is still (1887) in force, in spite of the recommendations of successive presidents and secretaries of the treasury for its repeal. The operation of refunding had been begun under the Act of July 14, 1870, authorizing the issue of 5, 4½, and 4 per cent. bonds, to take the place of those at higher interest which should be payable. This first refunding operation was completed in the year of the resumption of specie payments (1879). The issues were \$500,000,000 at 5 per cent., \$185,000,000 at 4½, and \$710,345,950 at 4, reducing the annual interest charge from \$81,639,684 to \$61,738,838. One secret of the success of the Government and its high credit was the persistence of the people in urging the payment of the national debt. The work was begun as soon as the war was ended; before all the

Demone-
stization
of silver.

Re-
funding.

Reduction of national debt.

soldiers had been sent home \$30,000,000 of the debt had been paid, and hardly a month has passed since without some reduction of the total amount. Between 1865 and 1880 the debt fell from \$2,850,000,000 to about \$2,000,000,000; and, as it decreased, the ability of the Government to borrow at lower interest increased. About \$200,000,000 of 6 per cent. bonds fell due in 1881, and the secretary of the treasury (Windom) took the responsibility of allowing the holders of them to exchange them for 3½ per cent. bonds, redeemable at the pleasure of the Government. This privilege was extended to about \$300,000,000 of other bonds, giving a saving of \$10,000,000 interest. The 4½ per cent. bonds of 1870-71 (\$250,000,000) are not redeemable until 1891, and the 4 bonds (\$738,000,000) until 1907. Roughly stated, the whole debt, deducting cash in the treasury, is under \$1,400,000,000, about \$1,100,000,000 being interest-bearing, the remainder non-interest-bearing, paper currency of different kinds.

Election of 1880.

323. In 1880 the Republicans nominated Garfield (p. 788) and Arthur (p. 787), and the Democrats Hancock (p. 789) and English. Again there was no great distinction between the party principles advocated. The Democrats, naturally a free-trade party, were not at all ready to fight a battle on that issue; and the Republicans, turning the contest to the point on which their opponents were divided, succeeded in electing their candidates. They were inaugurated in 1881; and the scramble for office which had marked each new administration since 1829 followed (§ 202). The power of the senate to confirm the president's nominations had brought about a practice by which the appointments in each State were left to the suggestion of the administration senators from that State. The senators from New York, feeling aggrieved at certain appointments in their State, and desiring the prestige of a re-election by their legislature, resigned. Unfortunately for them the legislature took them at their word, and began to ballot for their successors. Their efforts to be re-elected, the caucuses and charges of treachery or corruption, and the newspaper comments made up a disgraceful scene. In the midst of it a disappointed applicant for office shot the president (July 2), and he died two months later. Vice-President Arthur succeeded him (§ 117), and had an uneventful administration. The death of President Garfield called general attention to the abominations of the system under which each party, while in office, had paid its party expenses by the use of minor offices for its adherents.

Assassination of Garfield.

Civil service reform.

The president's power of appointment could not be controlled; but the Pendleton Act (1883) permitted the president to make appointments to designated classes of offices on the recommendation of a board of civil service commissioners. President Arthur executed the law faithfully, but its principle could hardly be considered established until it had been put through the test of a Democratic administration; and this consideration undoubtedly had its influence on the next election (1884). The Republicans nominated Blaine and Logan, and the Democrats Cleveland and Hendricks. A small majority for the Democratic candidates in the State of New York gave them its electoral votes and decided the election in their favour. They were inaugurated (1885), and for the first time in more than fifty years no general change of office-holders took place. The Pendleton Act was obeyed; and its principle was applied to very many of the offices not legally covered by it. There have been, however, very many survivals of the old system of appointment, and each of them has been met by a general popular disapproval which is the best proof of the change of public sentiment. At least, both parties are committed to the principle of civil service reform. There is a growing desire to increase

the number of offices to which it is to be applied; and the principle is making its way into the administration of States and cities.

324. At home and abroad there is not a cloud on the political future of the United States in 1887. The economic conditions are not so flattering; and there are indications that a new era of struggle is opening before the country, and that it must meet even greater difficulties in the immediate future. The seeds of these may perhaps be found in the way in which the institutions of the country have met the new economic conditions which came in with the railway in 1830.

325. Corporations had existed in the United States before 1830, but the conditions, without the railway or telegraph, were not such as to give them pronounced advantages over the individual. All this was changed under the new régime; the corporation soon began to show its superiority. In the United States at present there are many kinds of business in which, if the individual is not very highly endowed, it is better for him to take service with a corporation. Individual success is growing more rare; and even the successful individual is usually succeeded by a corporation of some sort. In the United States, as in England, the new era came into a country which had always been decided in its leanings to individual freedom; and the country could see no new departure in recognizing fully an individual freedom of incorporation (§ 215). Instead of the old system, under which each incorporation was a distinct legislative act, general provisions were rapidly adopted by the several States, providing forms by which any group of persons could incorporate themselves for any purpose. The first Act of the kind was passed in Connecticut in 1837, and the principle of the English Limited Liability Act of 1855 was taken directly from it. The change was first embodied in New York in its constitution of 1846, as follows:—"Corporations may be formed under general laws, but shall not be created by special Act, except for municipal purposes and in cases where, in the judgment of the legislature, the objects of the corporation cannot be attained under general laws." The general laws were for a long time merely directions to the corporators as to the form of the certificate and the place where it was to be deposited. The New York provision was only a development of the principle of a statute of 1811 applying to manufacturing, but it is an instance of what was taking place all over the country.

Corporations in the United States.

Freedom of incorporation.

326. The consequent freedom of corporations was also influenced by the law, as expounded by the Supreme Court of the United States in the "Dartmouth College case" (1819), whose principle has always been the object of vigorous but unsuccessful criticism. The States are prohibited by the constitution from passing any laws which shall alter the obligation of contracts. This decision held that a charter was a contract between the State and the corporation created by it, and therefore unalterable except by consent of the corporation. The States were careful thereafter to insert in all charters a clause giving the State the right to alter the charter; but the decision has tended to give judges a bias in favour of the corporations in all fairly doubtful cases. Corporations in the United States thus grew luxuriantly, guarded by the constitution, and very little trenched upon by the States.

Dartmouth College case.

327. American corporations have usually been well managed, and very much of the extraordinary development of the wealth of the United States has been due to them. But a corporation which holds \$400,000,000 of property, owns more than one State legislature, and has a heavy lien on several others, is not an easy creature to control or limit. Wars of rates between rival corporations

Corporate power.

claiming great stretches of territory as "their own," into which other corporations must not intrude, are startling things to any people. The rise of a corporation, built upon the ruins of countless individual business concerns, and showing that it can reduce railway corporations to an obedience which they refuse to the State, is too suggestive of an *imperium in imperio* to be pleasant to a democracy. The States, to which the whole subject legitimately belongs, confess their inability to deal with it by leaving Congress to pass the Inter-State Commerce Act (1887), intended to stop the encroachments of railway corporations on individual rights (§ 106); but the success of even this measure is still quite doubtful.

Inter-State
Commerce
Act.

Corpora-
tions
as em-
ployers.

328. Still more unhappy have been some of the effects of the new régime on the relations between employers and employed. The substitution of a corporation for an individual as an employer could not but affect such relations unhappily, at least for a time; but the freedom and power of the corporate employers strained the relations farther than was at all necessary. The first clumsy attempts to control the corporations, by limiting the percentage of their profits, led to the artifice of "watering," or unnecessarily increasing, their stock. In good years the nominal dividends were thus kept down to an apparently normal percentage. When bad years, or increasing competition, began to cut down the dividends, the managers were often forced to attack the wages, or increase the duties, of their employees. The "bad years" began to be more numerous and constant after the financial crisis of 1873 had set in; and the first serious effects appeared in the "railroad strikes of 1877."

Con-
centra-
tion of
popula-
tion.

329. For many years past, the drift of population had been towards an urban life. Taking the town of 8000 inhabitants as the lower limit of urban population, we find that 3·3 per cent. of the population was to be classed as urban in 1790, and that the percentage had risen to 22·5 in 1880. If towns of 4000 inhabitants had been taken as the lower limit, the urban population in 1880 would have been 13,000,000, or more than 25 per cent. It may be thought that the policy of protection, of abnormal stimulation of manufactures, had something to do with this tendency; but it is noteworthy that the increase during the generally free-trade period of 1840-60, from 8·5 to 16·1, was the greatest of any twenty years, unless we take the period 1850-70, half free-trade and half protective, when the percentage rose from 12·5 to 20·9. Whatever may have been the cause, the tendency is indubitable, and its effects in increasing the facility of organization among the employees of corporations, whose fields of operation are generally urban, are as easily to be seen.

Popular
feeling
towards
corpora-
tions.

330. Some of the corporations were controlled by men who were believed, in some cases on the best of evidence, to have gained their control by the defects of American corporation law, particularly by the privilege of the majority of stock-holders to use the whole stock almost at their discretion, even for the wrecking of the road and its repurchase on terms ruinous to the minority's interests. Disrespect for "property rights" thus acquired was apt to extend to other corporate property, acquired legitimately: in the railroad strikes of 1877, there were cases in which citizens usually law-abiding watched with hardly-concealed satisfaction the destruction of such property as belonged to corporations. Further, the neutral position of the United States had brought about the transfer of considerable English and other foreign capital to the United States to be invested, under corporate privileges, in cattle-ranges or other industries connected with Western agriculture. The American managers of these corporations, feeling little responsibility to any power except their foreign employers, permitted themselves to take liberties with individual

settlers and their rights which arrayed a large part of the agricultural population of the West against corporate property. Finally, the differential rates made in private, even secret, contracts, by railway corporations all over the country, had gathered up passions of all sorts against the corporate "monopolies." The anchor of agricultural conservatism, usually a safe reliance in the United States, had ceased to be of service in this matter. An order, the "Patrons of Husbandry," said to number 1,500,000 members in 1874, had been formed with the avowed object of checking the common corporate enemy; and, though its prominence was short-lived, its influence remained.

"Patrons
of Hus-
bandry."

331. The growing power of corporations, and that at a time when the democracy had just shown its strength most forcibly and to its own satisfaction; the evident tendency of the corporations, especially in the protected industries and in transportation, to further combinations, such as "pools" and "trusts"; the consequent partial disappearance of that competition which had seemed to be a restriction on the power of the corporations over the individual; the power and disposition of corporations to cut wages down whenever dividends made it necessary to do so; the half-understood, but heartily dreaded, weapon known as the "black list," by which combinations of employers, especially of corporations, drove employees inclined to "agitation" out of employment; the general misgivings as to the wisdom or honesty of the State legislatures, in which the power over corporations was vested; the unhappy influences of the increase of urban population over the jury system; the complicated systems of appeals which had grown up in American law, with their opportunities for delay or perversion of justice by wealthy and determined corporations; the altered character of American labour, which was now largely made up of a mass of immigration hardly yet fully digested, and more apt than American labour had once been to seek help in something else than individual effort,—all these influences made up a mass of explosives which became seriously dangerous after 1880. It was no longer so easy for the individual to defend himself against corporate aggression; if it had been, the American working man was no longer so apt to trust to an individual defence; and labourers began to turn to combinations against corporations, though these combinations were even more prompt and successful in attacking individual employers than in attacking corporations.

332. The trade unions, which retained most of the conservative influences of their generally beneficiary nature, were not radical enough; and a local Philadelphia society, the "Knights of Labour," was developed into a national organization, following the usual American system of local "assemblies," with delegates to State and national conventions. With but 52,000 members in 1883, it claimed 630,000 in October 1886, and 1,000,000 at the beginning of 1887. Its general object was the union of all classes and kinds of labour into one organization, so that, "an injury to one being the concern of all," the oppression of even the humblest and weakest individual might be answered by the sympathetic action of more important and, if necessary, of all classes of labour. The "boycott," an imported idea, was its most successful weapon: the firm or corporation which oppressed its employees was to be brought to terms by a refusal of all members of the national organization to buy its productions, or to deal with any one who bought or sold them. Such a scheme was directly subversive of all social protection or security; and yet it had gone on for nearly two years before it came plainly to public notice (January 1886). Boycotts increased in number; local assemblies, intoxicated by their sudden success, went beyond the control of the well-intentioned head of the order; the passive obedience on the part of

Trade
unions.

"Knights
of Labour."

The
boycott.

Anti-
social
results.

the members, which was a necessary feature of the system, evolved a class of local dictators, or "rings," which were irresponsible as well as tyrannical; and the business of the country was very seriously threatened all through the years 1886 and 1887.

333. Law has begun to pronounce distinctly against both the black list and the boycott, as well as against the systems based upon them. There can be no doubt of the cruel tyranny which the new system of labour organization tends to erect not only over its enemies, the class of employers and those working men who are not of the order, but over its own members. But the demonstration of the illegality and tyranny does not alter the conditions of the problem, of which it is but a single phase. How are the English common law, its statutory development, and its jury system, to exist when a great mass of the population is discontented, distrustful, and under the dominion of a secret public opinion, and when the way does not seem to be open for a removal of their discontents except by the serious curtailment of the corporate system which has been so powerful an agent in American development and wealth? The great American republic, then, seems to be entering upon a new era, in which it must meet and solve a new problem—the reconciliation of democracy with the modern conditions of production.

The new era.

Bibliography.

The works treating of the various phases of the history of the United States are so numerous that only the names of the leading authorities can be given:—The histories of the United States by Bancroft (to 1783), Pitkin (to 1797), Ramsay (to 1814), Hildreth (to 1820), Bradford (to 1840), Tucker (to 1840), Spenser (to 1857), Bryant and Gay, Schooler, Von Holst, Higginson; McMaster, *History of the American People*; Gilman, *History of the American People*; Winsor, *Narrative and Critical History*; Williams, *Statesman's Manual*; H. H. Bancroft, *History of the Pacific Coast*; The American Commonwealth Series; Force, *Tracts relating to the Colonies, and American Archives*; Poore, *Federal and State Constitutions*; Hazard, *Historical Collections*; Neill, *English Colonization in America*; Dodge, *English Colonies in America*; Doyle, *English Colonies in America*; Burke, *English Settlements in America*; Holmes, *Annals of America*; Graham, *History of the United States*; Marshall, *History of the Colonies*; Palfrey, *History of New England*; Parkman's Works; Gordon, *History of the Independence of the United States*; Winsor, *Reader's Handbook of the Revolution*; Carrington, *Battles of the Revolution*; Ludlow, *War of American Independence*; Frothingham, *Rise of the Republic*; Story, *Commentaries*; Chalmers, *Annals of the Colonies, and Revolt of the Colonies*; Scott, *Constitutional Liberty in the Colonies*; Journals of Congress, 1774-89; *Annals of Congress, 1789-1824*; *Register of Debates in Congress, 1824-37*; *Congressional Globe, 1833-72*; *Congressional Record, 1872-87*; *American State Papers (to 1815)*; Benton, *Abridged Debates of Congress (to 1850)*; *United States Statutes at Large*; *Revised Statutes of the United States*; Niles, *Weekly Register, 1811-36*; *Tribune Almanac, 1838-87*; Appleton, *Annual Cyclopædia, 1881-86*; Spofford, *American Almanac, 1878-87*; M'Pherson, *Political Manuals*; Greeley, *Political Text-Book, 1860*; Cluskey, *Political Cyclopædia, 1860*; Hamilton, *Republic of the United States*; Renton, *Thirty Years' View*; Young, *American Statesman*; Johnston, *History of American Politics*; Stanwood, *History of Presidential Elections*; Porter, *Constitutional History*; Story, *Commentaries on the Constitution*; Kent, *Commentaries on American Law*; Wharton, *Commentaries*; Duer, *Constitutional Jurisprudence*; Brownson, *American Republic*; Milford, *The Nation*; The Federalist; Jameson, *Constitutional Convention*; "Centz," *Republic of Republics*; Tucker, *Blackstone's Commentaries*; Curtis, *History of the Constitution*; Bancroft, *History of the Constitution*; Elliot, *Debates*; Cooley, *Constitutional Limitations, Tarration, and Constitutional Law*; Sedgwick, *Statutory and Constitutional Law*; Bump, *Notes of Constitutional Decisions*; Wilson, *Congressional Government*; Fiske, *American Political Ideas*; M'Crary, *Election Laws*; Rorer, *Inter-State Law*; Lamphere, *American Government*; Counting the Electoral Vote, 1877-1876; M'Knight, *Electoral System*; Dillon, *Municipal Corporations*; Morse, *Citizenship*; Lalor, *Political Cyclopædia*; Burnett, *Settlement of the North-West Territory, 1847*; Flint, *Geography and History of the Mississippi Valley, 1823*; Histories of the various States; Bishop, *History of American Manufactures*; Seybert, *Statistical Annals*; Pitkin, *Statistical View, 1816*; De Bow, *Industrial Record of the South and West, 1852*; *Eighty Years' Progress of the United States, 1861*; *First Century of the Republic, 1876*; *Compendium of the Census, for 1850, 1860, 1870, and 1880*; Walker, *Statistical Atlas, 1874*; Scribner's *Statistical Atlas, 1884*; Reports of the Bureau of Statistics, 1866-87; Lyman, *Diplomacy of the United States*; Truscot, *Diplomacy of the Revolution, and Diplomatic History, 1797-1801*; Baker, *Diplomatic History, 1861-65*; Reports of the Secretary of the Treasury; Cooper, *History of the Navy (to 1858)*; Emmons, *History of the Navy (to 1858)*; Preble, *History of the American Flag*; Roosevelt, *Naval History of the War of 1812*; Boynton, *History of the Navy, 1861-65*; Porter, *Naval History of the Civil War*; Williams, *History of the Negro Race*; Wilson, *Rise and Fall of the Slave Power*; Goodell, *Slavery and Anti-Slavery*; Hurd, *Law of Freedom and Bondage*; Hammond and others, *The Pro-Slavery Argument*; Stephens, *War between the States*; Blaine, *Twenty Years in Congress*; Official Records of the Civil War; *Rebellion Record*; Personal Narratives of Grant, Sherman, McClellan, J. E. Johnston, Hood, and Beauregard; Reports of the Committee on the Conduct of the War; Scribner, *Campaigns of the Civil War*; *Battles and Leaders of the Civil War*; Comte de Paris, *History of the Civil War in America*; Greeley, *American Conflict*; Draper, *History of the Civil War*; Pollard, *Lost Cause*; Davis, *Rise and Fall of the Confederate Government*; *American State Papers on Finance (to 1828)*; Bolles, *Financial History of the United States*; Sumner, *History of American Currency*; Gouge, *Paper Money in the United States*; Spalding, *Legal Tender Paper Money*; Knox, *United States Notes*; H. C. Adams, *Public Debt*; Gibbons, *Public Debt of the United States*; Reports of the Secretary of the Treasury; Wells, *Internal Revenue Commission Report, 1866*; Tansig, *Protection to Young Industries, and History of the Present Tariff, 1860-83*; Young, *Tariff Legislation of the United States, 1870*; Hadley, *Railroad Transportation*; Poor, *Railroad Manual*; Adams, *Railroads: their Origin and Problems*; Hudson, *Railways and the Republic*; Ely, *Labour Movement in America*; Reports of the Bureau of Statistics of the various States.

The Presidents and Vice-Presidents of the United States.

Terms.	Presidents.	Vice-Presidents.
1789-93	1. George Washington, Va.	1. John Adams, Mass.
1793-97	George Washington.	John Adams.
1797-1801	2. John Adams, Mass.	2. Thomas Jefferson, Va.
1801-05	3. Thomas Jefferson, Va.	3. Aaron Burr, N.Y.
1805-09	Thomas Jefferson.	4. George Clinton, N.Y.
1809-13	4. James Madison, Va.	George Clinton (d. 1812).
1813-17	James Madison.	5. Elbridge Gerry, Mass. (d. 1814).
1817-21	5. James Monroe, Va.	6. Daniel D. Tompkins, N.Y.
1821-25	James Monroe.	Daniel D. Tompkins.
1825-29	6. John Quincy Adams, Mass.	7. John Caldwell Calhoun, S.C.
1829-33	7. Andrew Jackson, Tenn.	John C. Calhoun, (res. 1832).
1833-37	Andrew Jackson.	8. Martin Van Buren, N.Y.
1837-41	8. Martin Van Buren, N.Y.	9. Richard Mentor Johnson, Ky.
1841-45	9. William Henry Harrison, O. (d. 1841).	10. John Tyler, Va.
1845-49	10. John Tyler.	
1849-53	11. James Knox Polk, Tenn.	11. George Mifflin Dallas, Pa.
	12. Zachary Taylor, La. (d. 1850).	12. Millard Fillmore, N.Y.
	13. Millard Fillmore.	
1853-57	14. Franklin Pierce, N.H.	13. William Rufus King, Ala. (d. 1853).
1857-61	15. James Buchanan, Pa.	14. John Cabell Breckinridge, Ky.
1861-65	16. Abraham Lincoln, Ill.	15. Hannibal Hamlin, Me.
1865-69	Abraham Lincoln (d. 1865).	16. Andrew Johnson, Tenn.
	17. Andrew Johnson.	
1869-73	18. Ulysses Simpson Grant, Ill.	17. Schuyler Colfax, Ind.
1873-77	Ulysses S. Grant.	18. Henry Wilson, Mass. (d. 1875).
1877-81	19. Rutherford Birchard Hayes, O.	19. William Almon Wheeler, N.Y.
1881-85	20. James Abram Garfield, O. (d. 1881).	20. Chester Alan Arthur, N.Y.
	21. Chester Alan Arthur.	
1885-89	22. Grover Cleveland, N.Y.	21. Thomas Andrews Hendricks, Ind. (d. 1885).

The following paragraphs contain a series of biographical notes on American public men, furnishing details of interest which could not without inconvenience have been incorporated in the foregoing continuous history.

ALLEN, ETHAN, was born in Roxbury, Conn., Jan. 10, 1737. He removed about 1766 to Vermont, where he became a leader of the Vermonters, or "Green Mountain Boys," in their struggle against New York. In 1775 he was the leader of the party which surprised Ticonderoga. He was captured in 1775, sent to England, and not exchanged until 1778. He died at Burlington, Vt., Feb. 12, 1789. He had published a number of somewhat eccentric pamphlets, either personal or attacks on Christianity. — See Spark's *American Biography*, vol. 1.

ANDREW, JOHN ALBION (1818-1867), governor of Massachusetts from 1861 to 1866, was born at Windham, Me., May 31, 1818. He became a graduate of Bowdoin College in 1837, and was admitted to the bar in Boston in 1840. He entered political life as a Whig, and the intensity of his anti-slavery convictions stood in his way until 1859, when he was sent to the State legislature. In 1860 he was elected governor. Foreseeing the coming struggle, he organized and equipped the militia of the State, and urged the other New England governors to do likewise. Lincoln's call for troops was received at Boston, April 15; Andrew had volunteers in motion the next morning; on the afternoon of the 16th three regiments were ready; the Massachusetts Sixth left Boston on the 17th, fought its way through Baltimore on the 19th, and reached Washington the same day. All through the war, Andrew's devotion to his duties was indefatigable, and it is to his influence that Massachusetts owes her place of pre-eminence in that great struggle. He died suddenly of apoplexy, October 30, 1867. P. W. Chandler has written a memoir of Andrew, and A. S. Brown a sketch of his official life.

ARNOLD, BENEDICT, was born at Norwich, Conn., Jan. 3, 1740. His disposition was unruly in his boyhood. When the revolutionary war broke out, he entered the army, and soon became a colonel. He was sent with a detachment through the Maine wilderness to assist Montgomery, and was severely wounded in the assault on Quebec in December, 1775. He was discontented because his promotion was slow, and still more because he had not sufficient opportunity for pecuniary advantage. Distinguishing himself at Bemis Heights and Stillwater, though then under arrest, he asked and obtained command of the post of West Point, the key to the Hudson river. He offered to betray this post to Clinton, but the negotiations were detected, and Clinton's agent, André, was captured and hanged as a spy, while Arnold escaped to the British lines. He was given a rank in the British army corresponding to that which he had abandoned, and commanded two plundering expeditions. It was not easy to induce other British officers to serve with him, and he went to England, where he seems not to have fared much better. He died in London, June 14, 1801. His *Life*, in Spark's *American Biography*, gives the usual American estimate of him; but a more apologetic biography, by a descendant, has recently been published.

ARTHUR, CHESTER ALAN (1830-1886), president from 1881 to 1885, was born in Fairfield, Vt., October 5, 1830, his father being a Baptist minister who had immigrated from Ireland. After graduating at Union College in 1848, he was a teacher for several years, and was admitted to the bar in New York in 1853. He rapidly obtained repute as a lawyer, particularly by his management of the cases of fugitive slaves; and, as quartermaster-general of the State of New York during the first two years of the civil war, charged with the duty of arming, equipping, and transporting the troops of the State, he obtained a reputation even higher. He became an active political leader in the Republican organization of New York city, and was appointed collector of the port by President Grant in 1871. Refusing to abstain from active political work, he was removed in 1878 by President Hayes; and in 1880, when Garfield had been nominated by the Republican convention, Arthur was nominated for the vice-presidency, in order to propitiate the supporters of Grant. He was elected with Garfield in November and inaugurated in the following March, and became president when Garfield died (Sept. 19). He proved an exception to the rule that vice-presidents succeeding to the office of president have been failures. To him belongs the credit of a quiet, dignified, and successful administration of public affairs, and, above all, the inception of the reform of the civil service system. He carried out the Pendleton Act for that purpose with honest good-will, and gave it an impetus which it is not likely ever to lose. He quieted the growing ill-feeling between his country and others as to South American affairs. The presence of British representatives at the hundredth anniversary of the surrender of a British army at Yorktown had a certain awkwardness, until the president's tact and good feeling relieved the pressure.

by ordering that the ceremonies should close with a general salute to the British flag, as a special mark of American respect for the queen. He finished his term with the high respect of all parties, and in the Republican convention of 1884 was the leading competitor for the nomination, which finally fell to Blaine. He died in New York city, November 18, 1886.

BELL, JOHN, was born near Nashville, Tenn., Feb. 15, 1797, and died near the same place, Sept. 10, 1869. He graduated at Nashville in 1814, became a lawyer, and served in the house of representatives, 1829-41, and in the senate, 1847-59, acting as secretary of war from March to October 1841. He was nominated for the presidency in 1860, and was defeated.

BENTON, THOMAS HART (1782-1858), was born near Hillsborough, N.C., March 14, 1782. Removing to Tennessee in 1799, he studied law, was admitted to the bar, and entered the life of a frontier lawyer and politician. Andrew Jackson, then the leading figure of Nashville, made him his aide-de-camp, and obtained for him the command of a Tennessee regiment. Quarrels and a street-fight in 1813, in which Jackson was nearly killed, made Tennessee an unpleasant residence for Benton, and, after two years of service as lieutenant-colonel of a United States regiment, he settled in St. Louis, Mo. From 1821 to 1851 he served as United States senator from Missouri. During all this period he was one of the most prominent members of the senate. He became a recognized leader of the Democratic party, and on the entrance of Jackson into national politics, he became one of his warmest supporters. Benton's knowledge of Spanish land-law made him an authority on all subjects into which that question entered; and his sympathy with the feelings of the Western settlers made him their mouth-piece on all such matters as the proposed annexation of Oregon. His pronounced aversion to all forms of paper currency procured him the popular name "Old Bullion," in which he took great satisfaction. Benton was always a pronounced Union man, and, when the slavery struggle had gone far enough to make the thought of disunion a political possibility, his supremacy in Missouri was over. He was defeated, after forty ballots, in the attempt to return to the senate for a new term in 1851. He served in the house of representatives, 1853-55, but was defeated in the next election as well as in the election for governor in 1856. He died at Washington, April 10, 1858. He has left two works of political value, *Thirty Years in the United States Senate* (2 vols.), and a most useful *Abridgment of the Debates in Congress from 1789 until 1850* (16 vols.).—See Roosevelt's *Life of Benton*, in the American Statesmen Series.

BOONE, DANIEL, born in Bucks county, Pa., Feb. 11, 1785, emigrated to North Carolina, penetrated the wilderness of Kentucky and began the settlement of that region, and died in Missouri, Sept. 20, 1820. Unlettered, but of strong native intelligence, simple honesty, courage, and coolness, he has become the type of his class.

BRAGG, BRAXTON (c. 1816-1876), American officer and general in the Confederate service, was born in Warren County, N.C., about 1815. He graduated at West Point in 1837, served in Florida and elsewhere for several years, and so distinguished himself in the Mexican war, particularly at Buena Vista, as to reach the rank of lieutenant-colonel by brevet. He resigned and retired to private life in 1856, but entered the Confederate service at the outbreak of the civil war with the rank of brigadier-general. He commanded at Pensacola, but was transferred to the west in 1862, soon reaching the full grade of general in command of the department of Mississippi. Just after Lee had begun his first attempt to invade the North in the east, Bragg began a similar attempt in the west. Passing to the east of the Union line in southern Tennessee, he moved northward into Kentucky, threatening Cincinnati, and remaining in Kentucky from August until October. The battle of Perryville (Oct. 8) forced him to retreat into Tennessee, but he carried off enormous trains of captured property and booty. Returning late in the year towards Nashville, he met Rosecrans in the battle of Murfreesboro or Stone River (Dec. 31, 1862-Jan. 2, 1863). It was very nearly a drawn battle, but Rosecrans held the ground, and slowly gained possession of the important point of Chattanooga during 1863. Following Bragg beyond it into Georgia, he was met and beaten in the battle of Chickamauga (Sept. 19-20, 1863), and Bragg, pursuing in his turn, formed the siege of Chattanooga. Grant replaced Rosecrans, and beat Bragg in the battles of Lookout Mountain and Missionary Ridge (Nov. 23-25, 1863), relieving the Union army. Bragg was then succeeded by Johnston, and took little further active part in the war. The Confederate president, Davis, retained Bragg at Richmond as military adviser. He died at Galveston, Texas, Sept. 27, 1876.

BRECKINRIDGE, JOHN CABELL (1821-1875), vice-president of the United States from 1857 to 1861, was born near Lexington, Ky., Jan. 21, 1821. He was admitted to the bar, served as major in the Mexican war, and was a Democratic member of the house of representatives from 1851 to 1855. He was elected vice-president in 1856 by the Democrats. In 1860 he was nominated for the presidency by the Southern wing of the Democratic party, but was defeated. Elected United States senator, he took his seat at the special session of July 4, 1861, left it (Aug. 6) to enter the Confederate army, and was expelled from the senate Dec. 4. He served at Murfreesboro and Chickamauga, and in the east, and in 1865 became the Confederate secretary of war. For a time he was in Europe, but returned in 1868, and died May 17, 1875.

BUCKINGHAM, WILLIAM ALFRED (1804-1875), governor of Connecticut, was born in Lebanon, Conn., May 28, 1804. In 1858 he was elected governor, and served until 1866. He refused further re-election, and retired to private life until 1869, when the Republicans of his State sent him to the United States senate, where he remained until 1875, the year of his death. His energy and foresight, as the "war governor" of his State, did for Connecticut what Andrew did for Massachusetts.

BURNSIDE, AMBROSE EVERETT (1824-1881), general in the Federal army, was born at Liberty, Ind., May 23, 1824. After graduating at West Point in 1847, he served in the Mexican war and on frontier duty until 1853, when he resigned. For five years he was engaged in the manufacture of firearms in Rhode Island, and for the next three years in the management of the Illinois Central Railway Company. He entered the civil war as colonel of Rhode Island volunteers, was given command of the land forces operating on the North Carolina coast, at Roanoke Island and elsewhere, and as major-general commanded the ninth corps of the army of the Potomac in the Antietam campaign. His management of the left wing in the final battle has been severely criticized by M'Clellan, on the ground of his slowness. When M'Clellan was relieved of the command of the army in November 1862, Burnside was made his successor. He undertook to follow the direct road to Richmond, across the Rappahannock and through Fredericksburg. He had hardly reached Falmouth, opposite Fredericksburg, when Lee had begun his lines of defence on the hills behind Fredericksburg. Burnside's army crossed the river Dec. 10-11, and Lee made the assault Dec. 13. Franklin on the left broke through the Confederate lines, but could not hold his ground; Sumner and Hooker led their men to the most dreadful slaughter of the war. On the night of the 15th of December the Union forces were withdrawn across the river, and Burnside resigned his command late in the following month, being succeeded by Hooker. Burnside served in the west during the year 1863, and commanded the ninth corps under Grant during the final Virginia campaigns. Re-entering civil life, he served as governor of Rhode Island, 1866-69, and as United States senator, from 1876 until his death in Rhode Island, September 13, 1881.

BURR, AARON (1756-1836), vice-president of the United States from 1801 to 1805, was born at Newark, N.J., Feb. 6, 1756, being the son of Rev. Aaron Burr, president of Princeton College, and grandson of Rev. Jonathan Edwards. He graduated at Princeton in 1772, served as an officer in the revolutionary army, becoming lieutenant-colonel, and in 1779 resigned and studied law. He began practice in New York, where the leading lawyers were disfranchised or under a cloud by reason of Toryism, and was successful almost at once, his leading competitor being Hamilton. He was a Republican United States senator, 1791-97, and introduced into the Republican party of his State that semi-military organization which now marks all successful parties. Presidential electors were then generally chosen by State legislatures, and Burr's skilful management obtained a legislature in 1800 with a Republican majority. The Republican leaders at Washington at once named him as the candidate to be voted for with Jefferson. All the Republican electors voted for the two, giving them a majority of the electoral votes, 73 each. But this, as the constitution then stood (§ 120), elected neither; the house of representatives was to choose between them. The house had a Federalist majority, and was disposed to make Burr president, in order to balk Jefferson and his party. It was not until the 36th ballot that Jefferson was chosen, and Burr never recovered his party's confidence. He was not re-nominated in 1804; and in the same year he shot his great rival, Hamilton, in a duel near New York city. In 1807 he was tried for an expedition against Mexico, but was acquitted. For some years he lived abroad, but in 1812 he returned to New York city and resumed the practice of law. He died on Staten Island, N.Y., Sept. 14, 1836. Burr's great ability, his influence over young men and over women, the immorality of his private life, the misfortunes of his career and the stoical patience with which he bore them, have made him a remarkable figure in American history. He is buried at Princeton, N.J.—See Parton's *Life of Burr*, Knapp's *Life of Burr*, Davis's *Memoir of Burr*, and *Private Journal of Burr*.

COLFAX, SCHUYLER, vice-president of the United States from 1869 to 1873, was born in New York city, March 23, 1823. At the age of thirteen he removed to South Bend, Ind., studied law, became a newspaper editor, and entered political life as a Whig, afterwards a Republican. Defeated in the Congressional election of 1851, he was successful at the next, and served in the house of representatives from 1855 to 1869. He was speaker of the house from 1863 to 1869. In 1868 he was nominated by the Republicans for the office of vice-president, and was elected, serving until 1873. He died Jan. 13, 1885. See Martin's *Life of Colfax* (1868).

CRAWFORD, WILLIAM HARRIS, American statesman, was born in Amherst county, Va., Feb. 24, 1772, but removed to Georgia while still a boy. He was admitted to the bar, served in the State legislature, 1803-7, in the United States senate, 1807-13, as minister to France, 1813-15, as secretary of war, 1815-16, and as secretary of the treasury, 1816-25. He was one of the leading aspirants to the presidency in 1816, but Monroe obtained the nomination by a small majority. As the end of Monroe's second term approached, it was thought that Crawford would certainly be his successor. In 1823 he was stricken with paralysis; but his friends endeavoured to conceal his condition, and pressed him for the caucus nomination in 1824. He obtained it, but it did him little service. Indeed, the struggle really put an end to the Congressional caucus as a nominating body. On his defeat he retired from national politics, serving as State judge in his own State from 1827 until he died at Elberton, Ga., Sept. 15, 1834. See J. B. Cobb's *Miscellaneous*, p. 181.

GARFIELD, JAMES ABRAHAM (1831-1881), president of the United States in 1881, was born at Orange, O., Nov. 19, 1831. His father died in 1833, leaving Garfield's mother to support four children, of whom the future president was the youngest. He learned the trade of a carpenter, earning some little additional money by working as a wood-chopper and as a driver on the canal. At the age of eighteen, he entered a village seminary, working at his trade and at odd jobs for his own support. After preparing himself for college, he carried himself in like manner through Williams College, graduating in 1856. He then became a professor in, and, after one year, president of, Hiram College, O., where he remained until 1861. During this period he studied law, and was admitted to the bar. He had also become a recognized leader of the Republican party of the State, being elected to the State senate for 1860-61. Entering the army as colonel of an Ohio regiment in 1861, he served in Kentucky and Tennessee, soon becoming brigadier-general and chief of staff to General Rosecrans. At Chickamauga he particularly distinguished himself, riding to Thomas's headquarters after the retreat of the rest of the army, and taking part in the gallant stand made by "the Rock of Chickamauga." For his services he was promoted to the rank of major-general. He resigned in December 1863, to take his seat in the house of representatives, to which he had been elected by his district in northern Ohio. This seat he never really left. He was re-elected steadily for the remainder of his life, his last term closing with the date of his inauguration as president. Just before this last event in his career, he was elected United States senator by the legislature of Ohio, but never took his seat. From his entrance to Congress in 1863 he was one of the most prominent Republican members; and in 1875, when the Republicans became for the first time since 1860 a minority in the lower House, he became their recognized leader there. In the Republican convention of 1880 he was ultimately nominated by 399 votes out of 756, and in November he was elected by an electoral vote of 214 to 155 for Hancock. He had always protested against the system which made the advice of administration senators the controlling factor in appointments to office; and yet, from the moment of his inauguration, he found himself entangled in a conflict about appointments with the senators from New York. In the midst of the newspaper excitement on this subject, a disappointed office-seeker shot the president in the Baltimore and Potomac railway station, July 2, 1881. After lingering through a Washington summer, he was removed (Sept. 6) to Long Branch, where he died on Sept. 19.

GRANT, ULYSSES SIMPSON (1822-1885), lieutenant-general in the United States army and president of the United States from 1869 to 1877, was born at Point Pleasant, O., April 27, 1822. He had but a slight education in his early youth, but graduated at West Point in 1843. He served in the Mexican war with credit, and in routine service until 1854, when he resigned, having then the rank of captain. His attempts to engage in farming near St. Louis and in the leather trade at Galena, Ill., were not successful; and, when the civil war broke out, he was the last man whom his brother officers would have picked out as the coming hero of the war. With some difficulty he obtained a commission as colonel of an Illinois regiment, but was soon advanced to the rank of brigadier-general, having his headquarters at Cairo, Ill. From this point he made incursions into the hostile territory, his first serious affair being at Belmont, Mo., Nov. 7, 1861, which was at best a drawn battle. The Confederate line ran through southern Kentucky, and was penetrated by the Tennessee river, of whose mouth Grant had possession. Estimating the opportunity correctly, he obtained permission, with much difficulty, to attempt to secure control of the whole Tennessee river. Flag-officer Foote, with seven gunboats and a number of transports, conveyed Grant's force up the river and captured Fort Henry, which commanded the point where the Confederate line crossed the Tennessee river (Feb. 6, 1862).

A distance of but seven miles separated the rifle-pits around this fort from those of Fort Donelson, which commanded the point where the Confederate line crossed the Cumberland river. Marching overland with about 15,000 men, Grant invested Fort Donelson, and began the first Federal siege of the war. The surrender of the fort (Feb. 16) broke up the Confederate line and forced it back into southern Tennessee. Grant was more popular with the general public than with his superiors, and his experience with them was so unpleasant that he asked to be relieved. Matters were patched up, and he was allowed to push southward. Here the battle of Pittsburgh Landing, in which Grant seems to have been taken by surprise, intensified the doubts his superiors had of his capacity, and he was for some time under a cloud, Halleck assuming command himself, and really retiring Grant for some months. A fully counterbalancing result of the battle was the establishment of perfect sympathy between Grant and Sherman, who had shared its dangers and what odium had come out of it. Grant himself has written that, in the Mexican war, his service "gave no indication that he would ever be equal to the command of a brigade," and that in 1861 he "had never looked at a copy of tactics since his graduation." His training for supreme command was now completed, and it had qualified him for the defence of Corinth, to which all his subsequent successes may be directly traced. Left there almost in isolation, and exposed to the attacks of all the forces which the Confederates chose to bring against him, his successful battles of Iuka (Sept. 19, 1862) and Corinth (Oct. 3-5) left him master of the route along the Mississippi. In January 1863 Grant and Sherman succeeded in taking the west bank of the Mississippi to a point opposite Vicksburg. Failing to reduce the city from this point, Grant crossed the river below Vicksburg in April, and began the remarkable campaign which ended with the surrender of Pemberton. It showed that he had strategic ability as well as fighting power, and that he was able to discern the characteristics of his opponents and to calculate on their probable errors, and it gave him an official as well as a popular respect which he never lost. Followed by the victories of Lookout Mountain and Missionary Ridge, it made him the acknowledged leader of the United States armies, and his appointment as lieutenant-general and commander-in-chief was a foregone conclusion. When Grant assumed command in Virginia in March 1864, Lee's unaccustomed tendency to maintain a strict defensive showed his underlying consciousness that he had before him at last a man who was ready and willing to answer an attack by a counter-attack. Grant's military ability had now reached its highest developments: he handled his 120,000 men with as complete control as he had shown with his 15,000 at Donelson. It is not probable that anything but the vigour and intensity of Grant's operations could have met successfully the problem offered to any commander by Lee behind intrenchments arranged by himself and manned by the army of northern Virginia, or could have reduced that army to the condition which it presented in the winter of 1864-65. The end of the war and the death of President Lincoln left Grant the foremost man of the North and West, and it was really inevitable that he should be elected president in 1868. From the moment of Lee's surrender the people had shown a disposition to put upon his shoulders any work which called for prompt completion. The Republican leaders relied on him to hold all that had been secured by the war until the Congressional plan of reconstruction should be fully carried out, and he did the work as probably no other man could have done it. His public life is really the history of the country for the eight years after 1869, and its errors were largely the result of the intrusion of some of his best personal qualities into it. The rule in the civil service still was that of appointment by favour of the political leaders of the dominant party; Grant, bewildered by the constant and tremendous pressure for appointments, undoubtedly selected some men who were no credit to his administration; when the appointment had been made, his own bitter experience of unjust criticism led him to look with suspicion on any accusation against those whom he had appointed; and his military habits of unquestioning obedience gave him a tendency to expect the same thing from men in politics, and to regard independence as a sort of treason, disqualifying the man guilty of it for any useful criticism. His second term was therefore filled with scandals which are likely to overshadow the solid and enduring achievements of his first. Retiring to private life, he found needed rest in a tour of the world; he was, however, a candidate for the Republican nomination for the presidency in 1880, and engaged in business in which he had no experience, and in which he lost his all. Attacked by an incurable disease, he spent his last few months of life in the preparation of his autobiography, knowing that its sale would be so large as to put his family out of reach of pecuniary distress. He died at Mount McGregor, N.Y., July 23, 1885.

HANCOCK, WINFIELD SCOTT (1824-1886), American officer, was born in Montgomery county, Pa., Feb. 14, 1824. He graduated at West Point in 1844, served with credit in Scott's campaign in Mexico and on frontier duty until 1861, when he held the rank of captain. Having been appointed brigadier-general of volunteers in 1861, he served in the army of the Potomac throughout its existence. For distinguished service on the peninsula and at South Mountain and Antietam, he was given a division and the rank of major-general, and in 1863 he was placed in command of the second corps for his services at Fredericksburg and Chancellorsville. His crowning glory was won at Gettysburg. Reynolds fell on the first day, and Hancock was sent forward by Meade to arrange the line until the commander could arrive. On the second and third days Hancock commanded the left centre, on Cemetery Ridge, where, just in the moment of victory, he was severely wounded. He received the thanks of Congress, and returned to the command of his corps early in 1864, in time to take part in Grant's campaigns of that year. He distinguished himself again and again at the Wilderness, at Spotsylvania, and in the Cold Harbor and Petersburg operations. At the end of the war he commanded various departments, having been made a major-general in the regular army. From September 1867 to March 1868 he commanded the department of the Gulf, under the Reconstruction Acts; and certain orders issued by him, particularly those of Nov. 29 and Dec. 5, 1867, declaring that the military power was meant only to uphold, not to control, the civil power, and declining to exercise arbitrary powers, were so satisfactory to the Democratic party that in 1880 it nominated him for the presidency. He was defeated by Garfield, but retained his position as senior major-general of the army, and the warm regard of the country. He died at Governor's Island, N.Y., Feb. 9, 1886.

HENDRICKS, THOMAS ANDREWS (1819-1885), vice-president of the United States in 1885, was born in Muskingum county, O., Sept. 7, 1819. He removed with his father to Shelby county, Ind., in 1822, graduated at Hanover College in 1841, and was admitted to the bar in 1843. He was a member of the State legislature in 1848-49, a Democratic member of the house of representatives, 1851-55, and commissioner of the land office, 1855-59. He served as United States senator, 1863-69, and as governor of Indiana, 1873-77. In 1876 he was nominated for the office of vice-president by the Democrats, but was defeated. In 1876, 1880, and 1884 he was a prominent candidate for the nomination for the presidency; and in 1884, when Cleveland was nominated, he consented to take the nomination for the vice-presidency, and was elected. He died at Indianapolis, Ind., Nov. 25, 1885.

HOOD, JOHN BELL (1831-1879), American officer in the Confederate service, was born at Owingsville, Ky., June 29, 1831. He graduated at West Point in 1853, and continued to serve in the United States army until 1861, when he entered the Confederate service. Rising rapidly from a first-lieutenancy to the command of the Texas brigade, he distinguished himself on the peninsula, in the seven days' battles at Antietam, and at Gettysburg, where he lost the use of an arm. He was now a major-general, and was sent to command a division in Bragg's army. He took a leading part in the battle of Chickamauga, where he lost a leg, but returned to duty within six months. He commanded a corps during Johnston's retreat before Sherman, in the early months of 1864; and, when Davis had decided on removing Johnston, Hood was appointed to the command of the army. He accepted reluctantly, and his position was not a pleasant one. He succeeded a general in whom the army had confidence; he was to reverse that general's policy, and he was to carry out a plan of campaign which had been prepared for him by the Confederate president. His obedience was painfully accurate. He assumed the offensive as soon as he took command, fought several severe battles, and soon found himself under necessity of evacuating Atlanta (Sept. 2, 1864). Sherman had outflanked him; and the Confederate administration came to the desperate resolution of ordering him to move west and then north into Tennessee. He was checked at Franklin, where he lost many of his best officers; and in the final battle of Nashville (Dec. 15) his army was completely beaten, and almost lost its organization. The command of its remnants was transferred to General Richard Taylor, and Hood retired from active service. He died of yellow fever at New Orleans, Aug. 30, 1879.

HULL, ISAAC (1775-1843), naval officer, was born at Derby, Conn., March 9, 1775. In 1798 he became lieutenant in the new navy created by Congress during the difficulties with France. He served with credit in the West Indies and Mediterranean, and, on the outbreak of war in 1812, was captain of the frigate "Constitution." By skilful seamanship he escaped the close pursuit of five British vessels, and on Aug. 19 he captured the British frigate "Guerriere" off Newfoundland, after a conflict in which the "Guerriere" was so severely cut up that Hull was forced to burn her. A gold medal was given him by Congress. He died at Philadelphia, Feb. 13, 1843.

KNOX, HENRY, major-general in the American revolutionary army, was born at Boston, July 25, 1750. Beginning life as a bookseller, he commanded an independent company in Boston, and was made an engineer and artillery officer by Washington at the opening of the revolution. Under his charge the artillery arm of the service came to be of essential value. He was made secretary of war in 1785, and Washington, on becoming president in 1789, gave him the same office under the new Government. He resigned in 1794, and retired to private life in Maine. He died at Thomaston, Me., Oct. 25, 1806.—See Drake's *Life of Knox* (1874).

LAWRENCE, JAMES (1781-1813), captain in the United States navy, was born at Burlington, N.J., Oct. 1, 1781, and entered the navy as a midshipman in 1798. He commanded the "Hornet" in the capture of the "Peacock," Feb. 24, 1813. Placed in command of the frigate "Chesapeake," he accepted the challenge of Captain Broke of the "Shannon" to a single battle, off Boston harbour. The "Chesapeake" was captured, and Lawrence, mortally wounded, died June 6, 1813.—See Irving's *Spanish Papers*, vol. ii.

M'CLELLAN, GEORGE BRINTON (1826-1885), general in the United States army, was born at Philadelphia, Dec. 3, 1826. He graduated at West Point in 1846, served in the Mexican war with such ability as to win the brevet of captain, and attained full rank as captain in 1855. His services until 1857 were mainly scientific, with the exception of a military report on the organization of European armies in 1856, the result of a commission from the Government to follow the progress of the Crimean War. In 1857 he resigned and entered the service of a Western railway, becoming its president. At the outbreak of the civil war he was engaged by Ohio as major-general commanding her volunteers, and was soon given the same rank in the United States army by President Lincoln. It fell to M'Clellan to cross into West Virginia and begin the campaign there, which he did during the early summer the campaign ending with the surrender of the Confederate forces at Rich Mountain and the expulsion of the opposing armies from his department, on July 14, 1861. This sudden and brilliant success, followed almost immediately by the collapse of the Manassas campaign against Richmond, brought M'Clellan into notice as the most likely leader to restore public confidence in the army of the Potomac. He was called to Washington, given command of the army, and, when Scott retired, was made commander of all the armies until March 1862, when his command was reduced again to the army of the Potomac. The winter of 1861-62 was spent in organizing his new army, and in the spring he was at last almost forced, by public outcry and the impatience of the administration, to attempt the task of wielding the weapon which he had created. Following what seems now the most feasible method of attack on Richmond, M'Clellan appears to have begun with little confidence in the administration, and it was not long before the administration lost confidence in him. His campaign on the peninsula is historical; but the time involved should be taken carefully into account in estimating M'Clellan's abilities. It was on Sept. 2 that he was recalled and given command of "all the troops for the defence of the capital." He found the armies in almost complete confusion; he organized and united them, marched them through Maryland to its northern border, attacked Lee's rear so vigorously at South Mountain as to force him to turn and fight, and defeated him after a two days' battle; and all this work was done in fifteen days, Sept. 2-17. He was removed, however, Nov. 7, 1862, for slowness in pursuing Lee, and Burnside became his successor. M'Clellan was nominated for the presidency in 1864, and had much difficulty in reconciling the peace platform of his party with his own feelings. Defeated by Lincoln, he retired to private business as a civil engineer, in which he was very successful. He was elected governor of New Jersey in 1877, serving 1878-81. He died at Orange Mountain, N.J., Oct. 29, 1885. The literature in attack and defence of his military reputation is voluminous; for his own version of his career see *M'Clellan's Own Story*.

MARCY, WILLIAM LEARNED (1786-1857), was born at Sturbridge, Mass., Dec. 12, 1786. He graduated at Brown University in 1808, was admitted to the bar in 1810, and began practice at Troy, N.Y. He soon became a leading Democratic politician, and one of the "Albany regency" which was supposed to control the action of the party in New York State. He was United States senator in 1831-32, and during his term he incidentally made use of the phrase so frequently afterwards heard, "To the victor belong the spoils." He resigned to become governor of New York, 1833-39. He was secretary of war under Polk, 1845-49, and secretary of state under Pierce, 1853-57. As secretary of state he conducted with success the Kosztka case in 1854, involving a collision with Austria on the subject of the right of expatriation. All his political leanings were to that branch of the Democratic party in New York which made the strength of the new Republican party in 1856, and he would have been its natural leader if he had followed his own convictions on the Kansas-Nebraska bill. He hesitated, and other men took his place. He died at Ballston Spa, N.Y., July 4, 1857.—See Jenkins's *Governors of New York*.

MASON, GEORGE (1726-1792), member of the Federal convention of 1787, was born in Fairfax county, Va., in 1726. He served in the Virginia conven-

tion in 1775, and drafted its Declaration of Rights and Plan of Government. His most conspicuous service was in the Federal convention of 1787, of which he was a member. He took part in most of the debates, and exerted a strong influence on the decision of almost every question before the convention. Some of his strongest utterances were on the subject of slavery, and his language on one occasion (Aug. 22) might have served as a model to an anti-slavery orator of later times. He was dissatisfied with the constitution, and opposed its ratification. He died Oct. 7, 1792.

MEADE, GEORGE GORDON (1815-1872), general in the United States army, was born in Cadiz, Spain, where his father was an agent of the United States navy, Dec. 30, 1815. He graduated at West Point in 1835, and, after serving but one year in the army, resigned to begin practice as a civil engineer. He was frequently employed by the Government, and re-entered its military service in 1842. He served with distinction on the staffs of Taylor and Scott in the Mexican war, and in scientific work. At the outbreak of the civil war he was placed in command of a brigade of volunteers, soon rising to the command of a division, and joining his fortunes permanently to those of the army of the Potomac. He led his division through the seven days' battles, being severely wounded at Glendale, through the Antietam campaign, and at Fredericksburg, where he particularly distinguished himself. At Chancellorsville he commanded the 5th corps; and when Hooker resigned the command of the army, and while the army itself was in hasty movement northward to check Lee's invasion of the North in 1863, Meade was appointed to the command. He accepted it with the greatest reluctance, and altogether from a sense of duty. He had inclined to fight on the line of Pipe Creek, to the south of Gettysburg; but Reynolds fell into collision with Lee's advance at Gettysburg, other corps hurried to support, and Gettysburg became historical. When Grant assumed general command in 1864, Meade continued to command the army of the Potomac under him, and mutual good-feeling enabled them to maintain this delicate relation without friction, and with the best results. At the close of the war, being major-general in the regular army, he commanded the military division of the Atlantic until his death at Philadelphia, Nov. 6, 1872.

MONTGOMERY, RICHARD, was born near Raphoe, Ireland, Dec. 2, 1736, and died in the assault on Quebec, Dec. 31, 1775. He served in the British army from 1754 to 1772, when he retired, emigrated to America, and settled in New York, marrying the daughter of R. R. Livingston. He was appointed a brigadier-general in the American army in 1775, and, for his services in Canada, was made a major-general the same year.

MORGAN, EDWIN DENNISON, governor of New York, was born at Washington, Mass., Feb. 8, 1811. After a successful career as a merchant in Hartford, Conn., and New York city, he served in the New York State senate, 1850-53, and was chairman of the Republican National Committee, 1856-64. Elected governor of New York in 1858, he served through the year 1862, supervising the raising and equipment of about 320,000 soldiers. He was United States senator, 1863-69. He died Feb. 14, 1883.

MORTON, OLIVER PERRY (1829-1877), one of the leaders of the Republican party, was born in Wayne county, Ind., Aug. 4, 1823. He was admitted to the bar in 1847, and was elected a circuit judge in 1852. He had been a Democrat, but became a Republican in 1855, and was the Republican candidate for the governorship in 1866. He was defeated, and in 1860 was nominated for the office of lieutenant-governor, with the understanding that the governorship candidate was to be sent to the United States senate, if possible. This arrangement took effect, and Morton was left to fill the office of governor throughout the civil war. He was active and successful in raising troops for the support of the Federal Government, and bold, almost to recklessness, in his means of action. He knew, or at least believed, that his political opponents in the State were determined to support the Confederacy by refusing to supply any more troops to the Federal Government; and the meeting of a hostile legislature in 1863 brought matters to a head. The Republicans left the legislature, thus leaving their opponents without a quorum; the governor ordered money for war expenses to be borrowed on the credit of the State; the Democratic attorney-general and the State Supreme Court held that this was illegal, but the indomitable governor borrowed the money on his personal responsibility, and managed the State government without a legislature. The borrowed money was afterwards repaid by the State. In 1866 he was elected to the United States senate, and remained till his death, taking a prominent part in every debate, and exercising a strong influence on the party policy. He introduced the resolution for the repeal of the twenty-second joint rule, which had governed the count of the electoral votes since 1865. He died at Indianapolis, Nov. 1, 1877.

PINCKNEY, CHARLES (1758-1822), American statesman, was born at Charleston, S.C., March 9, 1758. He was admitted to the bar in 1779, was a delegate to the Continental Congress, 1777-78 and 1784-87; a delegate to the Federal convention of 1787; governor of South Carolina, 1789-92 and 1796-98; United States senator (Democrat), 1797-1801; minister to Spain, 1803-5; governor of South Carolina, 1806-8; member of the State legislature, 1810-14; and member of the house of representatives, 1819-21. He died at Charleston, Feb. 25, 1822.

PINCKNEY, CHARLES COTESWORTH (1746-1825), born at Charleston, S.C., Feb. 25, 1746, and died at the same place, Aug. 16, 1825. He was educated at Oxford and the Middle Temple, served with distinction in the American revolutionary army, was one of the envoys to France in 1797, and was the Federalist candidate for the presidency in 1804 and 1808.

PULASKI, CASIMIR, COUNT, born in Lithuania, March 4, 1747, joined in the insurrection of 1769, escaped to Turkey in 1772, and was induced by Franklin to emigrate to America in 1777. He served in the battles of Brandywine and Germantown, receiving the rank of brigadier-general for his gallantry, and was placed in command of the cavalry. Forming a separate corps, known as Pulaski's legion, he went to the South, where he commanded the cavalry in the assault on Savannah. He was mortally wounded, and died Oct. 11, 1780.—See *Spark's Life of Pulaski*.

PUTNAM, ISRAEL, was born at Salem, Mass., Jan. 7, 1718, removing to Pomfret, Conn., in 1739. Courage, strong will, and knowledge of men rather than of books soon made him a leader among his neighbors; and his shooting of a wolf by torch-light in a cavern in which she had sought refuge has almost become a nursery story. In the French and Indian war he became one of the most renowned of the "rangers" or partisan soldiers, who fought the Indians with their own weapons; and at the end of the war he had reached the rank of lieutenant-colonel of the Connecticut troops. At the outbreak of the revolutionary war, one of the four major-generals' commissions was given to Putnam. He was an active leader at Bunker Hill, commanded at New York, and in the battle of Long Island, and was put in charge of the Hudson river defences in 1777, being the first to see the strategic importance of West Point. He died at Brooklyn, Conn., May 19, 1790.—See *Lives* by Cutler, Humphreys, and Peabody.

SCHUYLER, PHILIP, American general, was born at Albany, N.Y., Nov. 20, 1733. He was of an old and wealthy Dutch family, and in early manhood became a leader in the affairs of the colony of New York. He reached the rank of major in the French and Indian war, and at the beginning of the revolutionary struggle was made one of the American major-generals. He took part in the expedition against Canada in 1775, but ill-health compelled

him to retire. He took the leading part in preparing to meet Burgoyne's expedition in 1778; but troops had to be called in from other States, and he was subjected to jealousies which thwarted him at every step. Nevertheless, his arrangements were so complete that he had really checkmated Burgoyne before Congress superseded him in the command by the appointment of Gates, who reaped all the glory which should have accrued to Schuyler. Retiring from the army, he served for three years in the Continental Congress, and in the United States senate, 1789-91 and 1797-98. He died at Albany, Nov. 18, 1804.—See *his Life and Times*, by Lossing.

SEXMOORE, HORATIO, governor of New York, was born at Pompey, N.Y., May 31, 1810. He was admitted to the bar in 1832, but never practised law, having a large private property. He soon became a leader of the Democratic party of the State, serving three terms in the State legislature after 1842, one of them as speaker. He was elected governor in 1852. In 1862 he was nominated again, and his success alarmed the national administration with a fear that the great State of New York would now be lukewarm or unfriendly. He proved to be one of the best of the "war governors," active, zealous, and prompt in raising and forwarding men and supporting the war, though he was accused of adopting temporizing measures with the draft mob in New York city in July 1863. He was nominated for the presidency in 1868, but was defeated by Grant, and then retired from public life. He died at Utica, N.Y., Feb. 17, 1886.—See *Croly's Life of Seymour* and *McCabe's Life of Seymour* (1868).

STEBBEN, FRIEDRICH WILHELM AUGUST HEINRICH FERDINAND, BARON VON, was born at Magdeburg, Prussia, Nov. 15, 1730. Entering the army at fourteen, he rose to be adjutant-general and staff-officer to Frederick the Great. After his retirement from active service, Deane induced him to go to America, where he was made major-general and inspector-general. He rendered eminent service by giving the army its first systematic drill. In this department he was the most important accession which the American army received from Europe. He settled as a farmer on land in what is now Steuben county, N.Y., given him by the State, and died there Nov. 28, 1794.—See *his Life* by Kapp, *Bowen's Life in Spark's American Biography*, and *Greene's German Element in the War of American Independence*.

SUMTER, THOMAS, was born in Virginia in 1734, and died near Camden, S.C., June 1, 1832. He removed to South Carolina when a boy, and entered the American army as lieutenant-colonel in 1776. When the British had apparently overrun the State he kept up the struggle, retreating, when hard pressed, to the swamps of the interior. He was made brigadier-general, and thanked by Congress. He was a representative for South Carolina from 1789 to 1793 and from 1797 to 1801, United States senator from 1801 to 1810, and minister to Brazil from 1810 to 1811.

TANEY, ROGER BROOKE, chief justice, was born in Calvert county, Md., March 17, 1777. He graduated at Dickinson College in 1795, and was admitted to the bar in Maryland in 1799. Like many other Federalists, he became a supporter of Jackson about 1820, and was called by him to the office of secretary of the treasury in 1833. The charter of the Bank of the United States contained a clause, allowing the secretary of the treasury to order the revenues to be deposited in other places than the bank, giving his reasons therefor to Congress. This clause was meant to cover the case of places where there was no branch bank; Jackson wanted to use it to cover a refusal to deposit any of the revenues in any of the branch banks or in the mother bank. Taney gave the necessary orders, and the bank was deprived of the further use of the revenues. The senate refused to confirm Taney in his position, but his real work in this office had been done. Taney succeeded Marshall as chief justice of the Supreme Court. The leading incidents of his career were his opinion in the Dred Scott case, and his attempt in 1861 to maintain the writ of *habeas corpus* against President Lincoln's suspension of it (the Merryman case). His life has been written by Tyler, and is in Van Santvoord's *Lives of the Chief Justices*.

THOMAS, GEORGE HENRY (1816-1870), general in the United States army, was born in Southampton county, Va., July 31, 1816. He graduated at West Point in 1840, and served on frontier duty and in the Mexican war. His fellow officers in the South unhesitatingly entered the Confederate service in 1861; but he declared for the Federal cause. He was sent at first into his native State, and then to the West, where he soon rose to the command of a division in the army of the Cumberland, with the rank of major-general. His victory of Mill Spring (Jan. 19-20, 1862) was the first encouraging event in the war in the West. He led his division in the advance on Nashville, and in all the campaigns leading up to the occupation of Corinth, of which place he was given command. He was now really second in command of the army of the Ohio, and distinguished himself at the battles of Perryville and Murfreesboro, but his reputation was fully made at Chickamauga. When the right of the army had been routed and was in full retreat on Chattanooga, Thomas, who had sustained the brunt of the attack of the first day, held his ground all through the second day against the whole Confederate army, retreated with persistent and stubborn fighting, covered the rest of the army and saved it from destruction, and gave so much time for fortification that Chattanooga was found by Bragg to be too strong for anything but a siege. From this time Thomas was in command of the army of the Cumberland, and held the centre at the storming of Missionary Ridge and in the campaigns up to the capture of Atlanta. When Hood undertook to transfer the war to Tennessee, Sherman left Thomas to oppose him. Thomas gathered up all his forces at Nashville, and inflicted a check on the advancing Confederates at Franklin (Nov. 30), but continued his preparations for a final battle near Nashville. His numbers were equal to those of Hood, but he persisted in refusing battle until he had prepared cavalry and made every arrangement for pursuit. Public clamour against Thomas's delay had become so loud that Grant had started from Virginia to assume command himself when Thomas attacked Hood (Dec. 15), routed him, and kept up so merciless a pursuit that the Confederate army was scattered almost beyond recovery. In 1869 he was transferred to the division of the Pacific, where he died at San Francisco, March 28, 1870. His name has come more and more to be synonymous with all that Americans regard as best in the character of a military leader.—See *Van Horne's History of the Army of the Cumberland*.

WHEELER, WILLIAM ALMON, vice-president of the United States from 1877 to 1881, was born at Malone, N.Y., June 30, 1819. He was admitted to the bar in 1843, served several terms in the State legislature and as president of the State constitutional convention of 1867, and was a member of the house of representatives from 1861 to 1877. He was nominated for the vice-presidency in 1876 by the Republicans, and was elected, after a contest before the electoral commission. He died at Malone, June 4, 1887.

WOODBURY, LEVI, was born at Francistown, N.H., Dec. 22, 1789, and was admitted to the bar in New Hampshire in 1812. He became a leader of the Democratic party of his State, was appointed to the supreme court of the State in 1816, was elected governor in 1823, and speaker of the State house of representatives in 1825, and served in the United States senate from 1825 to 1831. He was secretary of the navy in 1831, and secretary of the treasury from 1834 to 1841. Again elected to the United States senate in 1841, he served until 1845, when he was appointed an associate justice of the United States Supreme Court. He died at Portsmouth, N.H., Sept. 7, 1851.—See *Democratic Review*, vols. ii. and xii. (A. J.)

PART II.—PHYSICAL GEOGRAPHY AND STATISTICS.

Copyright, 1888, by Josiah D. Whitney.

PHYSICAL GEOGRAPHY AND GEOLOGY.

Plate VIII. The area of the United States extends, throughout nearly its whole breadth, from the Atlantic to the Pacific. The northern edge of the vast indentation made in the continent by the Gulf of Mexico marks the southern boundary between the meridians of 88° and 97°. From the edge of this gulf the boundary between the United States and Mexico is partly artificial. Its most essential feature is the Rio Grande, which separates the two countries from 31° 47' N. lat. to its mouth. The boundary between the United States and Canada is to a large extent natural; though artificial in the north-east (see map), it follows the St Lawrence and the Great Lakes from the 45th parallel to the point where the Rainy Lake river enters Lake Superior, and thence passes up that river to a point on the west side of the Lake of the Woods, whence it goes along the 49th parallel to the Georgia Gulf. The country, as thus limited, excluding Alaska, comprises an area, according to the most recent determinations of the Census Bureau, of 3,025,600 square miles. This total includes 55,600 square miles of water surface (coast waters, bays, gulfs, sounds, &c., 17,200; rivers and smaller streams, 14,500; lakes¹ and ponds, 23,900). The area of Alaska is given in the Census Report of 1880 as 581,409 square miles,—a rough approximation, differing greatly from that given in the 1886 Report of the commissioner of the General Land Office. The total area possessed by the United States is therefore, approximately, 3,557,000 square miles.

Geo-graphical position. The longitude of the most easterly point is about 67° W.; that of the most westerly nearly 125°. The parallels of 29° and 49° N. roughly designate the position of the country in reference to latitude. The extreme southern end of Florida, however, extends as far south as 25° N., while the northern extremity of Maine only reaches to a little beyond 47° N., the large triangular area between the St Lawrence and the Great Lakes, belonging to Canada, being all south of the 49th parallel.

Coast. As compared with the western coast of Europe, neither side of America possesses a deeply indented coast-line. On the Pacific side there is only one important bay (that of San Francisco) between San Diego and Puget Sound. At San Francisco and San Diego there are commodious harbours, but within the limits of the United States there are no others on the Pacific coast, unless we except that furnished on the extreme north by Puget Sound, and that offered by the mouth of the Columbia river, the bar of which is somewhat formidable except for steamers under the management of skilful pilots.

The eastern coast north of the 35th parallel is a considerably broken one. That of Maine may almost be described as a "fiord coast," so numerous are the indentations, which are, however, of moderate depths, but which are large enough to afford excellent and commodious harbours, of which that of Portland may be taken as the type. There is an indentation of considerable size formed by the arm of Cape Cod projecting almost at right angles, and enclosing Massachusetts Bay, at the bottom of which lies the commodious, but not specially accessible, harbour of Boston. The situation of the city of New York makes it by far the most important centre of foreign and domestic commerce in the United States. This superiority is due in part to the excellence of its harbour, and in part to its being the terminus of the great natural line of communication between the East and the West, a position which would seem to belong by right to some point on or near the mouth of the St Lawrence, which is the outlet of the Great Lakes, but from which this river is shut out by its north-easterly trend, which carries it into a region beyond that of successful cultivation and populous settlements, and where navigation is suspended during a considerable portion of the year by the freezing of the river.

Long Island, about 120 miles in length, and extending along the southern coast of Connecticut, is the only island of any considerable size on the whole Atlantic coast. Smaller ones—Martha's Vineyard, Nantucket, Block Island, and others—lie adjacent to Long Island on the east, and form, as it were, its prolongation in that direction, while there are indentations of considerable depth on the coast of the mainland opposite these islands.

South of New York there are two indentations of importance—Delaware Bay and Chesapeake Bay,—the former being, as it were, the expanded mouth of the river of the same name, the other being in somewhat similar relations to two large rivers, the Susquehanna and the Potomac. Philadelphia and Baltimore are the cities that command the advantages for commerce which these two bays offer.

The Gulf of Mexico is of large dimensions, and of great importance as affecting the accessibility of the interior, and still more as influencing the climate of the country. The peninsula of Florida, extending 5 degrees south of the mainland, and forming the eastern boundary of the Gulf, is in a considerable part of its surface so low and swampy as to be practically uninhabitable.

The drainage areas of the country, as given by the United States Drainage census of 1880 are—Atlantic and Gulf, 2,178,210 sq. m.; Great areas. Basin, 228,150; Pacific slope, 619,240. The drainage into the Atlantic and Gulf is distributed as follows:—New England coast, 61,880 sq. m.; Middle Atlantic coast, 83,020; South Atlantic coast, 132,040; Great Lakes, 175,340; Gulf of Mexico, 1,725,980 (the Mississippi-Missouri basin being estimated at 1,240,039).

The explanation of this overwhelming preponderance of drainage into the Gulf of Mexico at once becomes evident when we notice the general relief of the country and the positions of the various watersheds. If the level of the ocean were raised 1000 feet, a broad water-way across the American continent would be opened. There would be a great mass of land on the western side, which would comprehend nearly the whole of Mexico, and which, within the limits of the United States, would have a breadth from east to west of from 1500 to 2000 miles. North of the United States boundary line the breadth of this mass of land would diminish rapidly in width as higher latitudes were reached, but its dimensions would still be on a grand scale, although deeply intersected with inlets occupying the positions of the lower portions of the present streams of that region. A similar rise of 500 feet in the ocean would not divide the continent into two decidedly distinct and widely separated parts, but would isolate New England from the land adjacent on the north and west, by opening a channel through the Hudson River and Lake Champlain depressions, would carry the Atlantic coast-line more than 100 miles inland of its present position, and would open a deep bay in what is now the Mississippi valley, the ramifying arms of which would extend north nearly to Chicago, to Cincinnati on the Ohio, to Burlington, Iowa, on the Mississippi, and nearly to Jefferson City, on the Missouri. A rise of sea-level¹ of 2000 feet would not materially change, as to position and size, the great land-mass on the western side of the continent already spoken of. That area would be slightly narrowed on the east, and would have its western edge more deeply indented, with the addition of groups of islands, so that its character would, south of the Columbia, be something like what it is at the present time north of that river. On the eastern side of the continent, however, the most striking changes would be effected. All the present coherent land-mass east of the 97th meridian would have disappeared, and in place of it we should have various groups of islands, one of the most important of which would extend from the north line of Georgia north-east into Pennsylvania and New Jersey, where it would terminate in finger-like projections, forming north-easterly and south-westerly trending archipelagos, with various outliers in north-eastern New York, Vermont, and New Hampshire, the highest points of which would rise from 3000 to 4000 feet above the surrounding waters. The distance of these islands from the western mainland would be from 1000 to 1500 miles. Another group of islands north of the United States boundary would extend in a curving line parallel to and north of the St Lawrence and the Great Lakes.

The all-important fact in the topography of the North American General continent in general, and of the United States in particular, is the topographical existence of a central comparatively low and level region, declining gently from a watershed in close proximity to the Great Lakes on the north towards the Gulf of Mexico on the south.

One may ascend the Mississippi to its junction with the Ohio, at Cairo—a distance of 1100 miles from the Gulf of Mexico,—and the elevation attained will be only about 300 feet, an average ascent of about 4 inches to the mile. A journey of almost 1000 miles farther, to Pittsburgh, at the junction of the Allegheny and Monongahela rivers, will only give a total rise of 700 feet above the sea-level. The head of the Mississippi is in a region entirely destitute of mountains, comprising an almost level area, covered in large part by lakes and swamps, and only about 1500 feet in elevation. In ascending the Mississippi to St Louis, a distance of 1250 miles, we have reached an elevation of about 400 feet, and at St Paul, 658 miles above the mouth of the Missouri, one of a little less than 700 feet. If we follow up the Missouri to the western line of the State of the same name, where the river flows from the north, we have the choice, if we wish to keep on directly west, of following either of its great branches from that direction—the Platte and the Kansas. Up either of these we may travel for fully 600 miles, rising so gradually that the difference of elevation from day to day is hardly perceptible, the country preserving all the characteristics of a plain, although declining gently to the east.

We have, therefore, in the central region of the United States a nearly level area, which, roughly speaking, may be taken at 1250 miles square, which has a very gentle downward slope from east and west to the centre, and from very nearly its northern extremity to the Gulf of Mexico, its southern boundary, while its northern edge, with a part of the adjacent region, is occupied by five great bodies of fresh water, communicating by short narrow river-like contractions of the water areas, and all together occupy-

¹ Under this head no portion of the Great Lakes is included.

ing an area of about 92,000 square miles. This central valley is not entirely devoid of mountains; but these higher areas are so small in extent, as compared with the entire area of the great valley, as to be of extremely subordinate importance. Meanwhile we turn to a consideration of the higher regions east and west of the great valley.

Neither on the eastern nor on the western side of the continent are these of the nature of simple mountain chains. On the contrary, both eastern and western highlands are complicated in their orographic structure, broken into portions, each having a character of its own, and generally—but not always—preserving a certain parallelism with each other, broken longitudinally or in the direction of the prevailing trend of the elevated mass, and separated by valleys and tablelands of very varying dimensions. The western mass, which is much the larger, is also very much the more complicated of the two. It is not only made up of a great number of parts more or less distinctly separated from each other, but it even encloses a large area of plains, valleys, and mountain ranges which have no drainage to the sea. This greatly predominating complexity of the western elevated region is the result of complicated geological conditions, to which are added climatic peculiarities of a striking character. The eastern elevated side of the continent is now generally called the Appalachian region, the western the Cordilleran.

The Appalachian System.

General character.

The Appalachian ranges all belong to an ancient system of uplift or disturbance, and have not been invaded by volcanic materials of recent date, presenting in both these respects a most marked contrast to the Cordilleran system. There are volcanic rocks along portions of the eastern slope of the Appalachians; but these eruptive dikes and overflows are not of Tertiary and post-Tertiary but of Mesozoic age.

The name Appalachian is used as designating the entire complex of ranges, valleys, and tablelands in and upon which is situated the watershed from which on the north and east the streams descend to the Atlantic, either directly or through the Great Lakes, and on the west and south-west to the Gulf of Mexico, either as tributaries to the Mississippi or flowing directly to the Gulf. As thus defined, the Appalachian region, system, or complex of ranges extends from the promontory of Gaspé, in a mean direction of north-east and south-west, to Alabama, a distance of about 1300 miles, where it disappears under the much more recent geological formations which form a broad belt along the Gulf of Mexico and extend far up the Mississippi valley.¹

While the Appalachian system, as a whole, is so nearly continuous, as a feature of the topography of the country, that it seems necessary to include it all under one general designation, yet different portions are extremely unlike each other in some of those features which are generally looked upon as essential to the unity of a mountain system.

Break of the Hudson and Mohawk.

One very marked and important break at least in the system is that occupied by the Hudson river, and extending up the Mohawk valley to the west, to a connexion with the Great Lakes, and up the Champlain valley to the north, to a connexion with the St Lawrence river direct. A rise of 152 feet in the sea-level would isolate from the rest of the continent all of New England and that part of Canada lying to the south-east of the St Lawrence, as far as the extremity of Gaspé. A further rise of 278 feet would open a waterway from the Atlantic to the Great Lakes, and leave the mass of the Adirondacks as an island lying adjacent to New England on the east and the Appalachian land-mass on the south. We seek in vain for any other break in the Appalachian system as complete as this, and, when we compare the portions of the system lying on each side of this line of division, we recognize the fact that there are essential points in which they differ from each other, and that these differences are greater than any presented by the various portions of the system in its extension to the south-west of the Hudson river break. This north-eastern division of the Appalachians may therefore properly first have its more important topographical and geological features indicated.

Beginning with the division west of Lake Champlain and north

¹ The first person to describe topographically the Appalachian system as a whole was Guyot, who, in 1861, published the results of several years' work among these mountains, giving the heights of numerous points obtained by the aid of the barometer, accompanied by generalizations in regard to the orography of the region, and a map (1:6,000,000), which was first published in *Petermann's Mittheilungen* (1860). The various geological surveys carried on by the States included in the Appalachian region have furnished a large mass of material both geographical and geological in regard to portions of the range; but, since this work has not, as a rule, been based on accurate topographical maps, most of it is rather of the nature of a reconnaissance than of a finished survey. The State of New Jersey is, however, publishing a map based on an accurate triangulation, but on a small scale (1:63,360). The first and second geological surveys of Pennsylvania have also done much to extend our knowledge of the topography of the most complicated and interesting portion of the whole Appalachian region, but as we go either south or north from this central region we find the data less and less complete, and in regard to the extreme south-western portion of the Appalachian range we are little if at all in advance of Guyot. What is most lacking at present is an accurate map of that portion of the system which lies to the south of the region embraced within the State of Pennsylvania.

of the Mohawk valley—the Adirondack region or mountains,—Adirondack we find, on examination, that this region is not only to a certain dacks, extent isolated topographically from the rest of the Appalachian ranges, but that it belongs to a geologically older system.² The rocks are all eruptive in the central portion of the mass, and chiefly gabbro and granitic or gneissoid in character. On the exterior, especially on the eastern edge, are deposits of limestone, which are generally believed by geologists to be sedimentary beds, highly metamorphosed; but which, in the opinion of the present writer, are more probably of the nature of chemical precipitates.

The drainage of this region is radial from a central point, but the slope on the east is shorter than on any of the other sides. From Tahawas or Mount Marcy (5344 feet) the drainage is to the north-east by the Au Sable to Lake Champlain, by the Raquette to the St Lawrence, and by the branches forming the head waters of the Hudson to the south. The dominating line of elevations runs nearly east and west, with high spurs and narrow ridges on the north, of which Whiteface Mountain (4871 feet) is one of the most conspicuous. The region is one of numerous lakes and lake-like expansions of the rivers, so that, with short portages, a large part of it can be visited by boat or canoe. The lake region proper of the Adirondacks lies at an elevation of from 1500 to 2000 feet:—Lake Silver, 1983 feet; Placid, 1950; Saranac (Upper), 1606, (Lower), 1557; Smith's, 1738; Tupper's, 1504; Long, 1584; Raquette, 1765; Sandford, 1685; Cranberry, 1570. There are indications of the Appalachian trend in the north-east south-west direction of several of the larger lakes; but many others trend nearly north and south. The number of the lakes is the result of the impermeability of the rock, the general uniformity in height of the region, and the broken character of the surface, which is very irregularly covered by large masses of rolled detritus. The work of water is everywhere distinctly visible, and that of ice hardly perceptible.

The mountainous region east of the Hudson in New England New is the portion of the system most irregular in topographical England features. Two groups of elevations, however, are quite well topographical marked, and have distinctive names—the Green and the White graphy. Mountains. These are separated by the Connecticut river, which has a nearly north and south course parallel to the range of the Green Mountains. Nowhere in this latter range is there a continuous uplift forming a long ridge or crest, but there is a gentle swell of the surface on which here and there rise elongated groups of considerably higher summits. In the extreme south-western corner of Massachusetts rises Bald Peak (2624 feet), and in the north-western corner Graylock or Saddle Mountain (3505 feet). Still farther north, in Vermont, are the culminating points of the Green Mountain range:—Equinox, 3872 feet; Pico, 3935; Camel's Hump, 4077; Killington, 4221; and Mansfield, 4389 feet. Ascutney, a quite isolated point, near the Connecticut river, has an altitude of 3163 feet.

The Connecticut river makes a very complete separation, in all but the extreme northern portion of its course, between the Green Mountain system and the highlands to the east, which have no collective name, but are in a measure the continuation of the White Mountain range. In Massachusetts this swell of land—for more it can hardly be called—has an elevation of about 1000 feet, the valleys being rarely sunk more than 200 or 300 feet below the general level of the gently undulating higher lands. Occasionally there is a higher point, like Wachusett (2018 feet) or Monadnock (3169 feet). From Monadnock the region east of the Connecticut broadens very much, the coast-line trending rapidly eastward. The country becomes more and more mountainous, but still without continuous ranges. The mountains are grouped around various central points, of which the most important are Moosilauke or Moosehillock (4790 feet), Lafayette (5290), and Washington (6290 feet). The last-named is the highest point in the Appalachian system north of North Carolina, and rises nearly 500 feet above all the adjacent summits.

Farther east, in Maine, and in the neighbouring portions of Canada, the topography has been little worked out in detail. So far as known, in Maine the irregularity of the range is still greater than it is farther to the south-west. There is in this part of New England no coast-region, but a gradual rise from the seashore towards the interior for about 140 miles, to the divide between the waters running into the Atlantic directly and those tributary to the St Lawrence or forming the head of the St John. This divide, which has a general direction of pretty nearly east and west, is at an altitude of about 1800 feet at the western edge of Maine, and declines to about 600 feet on its eastern boundary. The southern slope is a very gradual one to the sea, and though broken and rocky is not diversified by any marked ridges or long elevations. The high points rise sometimes nearly isolated, and sometimes in clusters, having little of the ridge character. Katahdin (Katahdin) is the

² The Adirondack region—or Adirondack Wilderness, as it is often called—has been more or less completely covered by a topographical survey made by authority of the State of New York; it was begun in 1872, but the final results, in the form of a map, have not yet been published.

dominating peak (5215 feet), and it rises in such isolation as to look in the distance like a volcanic cone. That part of Maine lying south of the watershed is drained by streams running nearly southward. Like the Adirondack Wilderness, it is a district of numerous lakes, as might be expected, since it has no rapid descent in any direction, is underlain by impermeable rocks, and has a considerable rainfall.

The general uniformity of character in the New England portion of the Appalachian system will be evident from what has been here stated. This region is marked by comparatively low swells of ground, on which rise groups of higher points, rather irregularly distributed, nowhere reaching the limit of perpetual snow, and nowhere presenting great obstacles to internal communication.

Geology
of New
England.

The geological structure of this north-eastern prolongation of the Appalachian system has been as yet only imperfectly made out, a circumstance due in part to the extreme scarcity of fossil remains, and in part also to the fact that the various sedimentary beds have been so metamorphosed as to be distinguishable only with great difficulty from the associated eruptive formations, while even the latter have frequently been themselves so much changed by chemical action, since their appearance at the surface, that it is only by the microscope that their real nature can be made out.

With the exception of a narrow belt of Mesozoic rocks in the Connecticut valley and a small basin of similar age in Woodbury and Southbury, Connecticut, and also with the exception of a very limited set of deposits of late Tertiary age on the eastern boundary of Lake Champlain and on the Atlantic coast, there are, so far as known, no rocks in New England more recent than the Palæozoic. Tertiary and Cretaceous formations are, however, found covering small areas on some of the islands adjacent to the coast. Along the western sides of Vermont and Massachusetts the rocks are clearly proved by their fossils to be of Lower Silurian age, and their structure has been made out in part. There are faults and synclinals,—limestones and chloritic and talcose slates being the predominating rocks. The dips are chiefly to the eastward, and the rocks are of more recent age as we go east from Lake Champlain, on the east side of which is a large development of the Potsdam sandstone. In and near the Connecticut valley, to the east of the region just noticed, fossils have been found (at Bernardston, Mass.) of late Upper Silurian age (Helderberg of the New York Survey). The stratigraphical relations of these rocks, however, remain obscure. The same may be said of nearly or quite all of New Hampshire, of eastern Massachusetts, and of a large part of Maine. At one point in New Hampshire (Littleton) fossils have been obtained of the same age as those discovered at Bernardston. In northern Maine, traversing the State in a wide belt running north-east and south-west, rocks occur of Upper Silurian and Lower Devonian age, well characterized by fossils, a part of this belt being clearly identical in age with the Oriskany sandstone of the New York Survey. The stratigraphical relations of these rocks are still obscure; and south of this fossiliferous belt is a wide area in which no fossils have yet been found. At one point in Massachusetts (Braintree, near Boston) more than fifty years ago fossils of the lowest Silurian age (Primordial) were found, and there are other indications that the rocks near the coast of New England, from Cape Cod north, are very low down in the fossiliferous series; but in Massachusetts, as well as in New Hampshire and Maine, there is a wide area between the Devonian and Upper Silurian rocks of the Connecticut valley and northern central Maine, of the geological age of which nothing is definitely known, and of which the stratigraphical relations are still very obscure.

The
Appalachians
south-
west
of the
Hudson.

To the west and south-west of the Hudson river, in New York, the intricacy and obscurity of the orographic structure and geological age of the Appalachian system begin to be cleared up; but it is not until we reach Pennsylvania that the characteristic features of this range are fully developed. (1) The first of these is, along its south-eastern edge, as we cross the system from south-east to north-west, at right angles to its trend, a series of elevations, at first comparatively unimportant and more or less detached from each other, but gradually, in going in a south-westerly direction, becoming more and more prominent and continuous, until, towards the extreme southerly end of the system, it forms the most imposing connected mass of high plateaus and still higher ridges anywhere exhibited in the Appalachian region. This south-easterly division of the system has no single distinguishing appellation. It is called in Pennsylvania the South Mountains, in Virginia the Blue Ridge; and in North Carolina and Tennessee it has various names applied to its different portions. (2) The second important feature is the Appalachian region proper of the First Pennsylvania Survey, a region of wave-like folds or corrugations, not so metamorphosed but that the geological sequence can be distinctly made out, in which orographic disturbances and a peculiar erosion have developed an interesting and intricate topography. (3) The third region, in crossing the chain from south-east to north-west, is that of plateaus, bounded on the south-east by an escarpment to which the name of Alleghany has been most frequently given, and by which that portion of the system which lies in Pennsylvania is

still almost universally known. These are the three most prominent divisions of the system south-west of the Hudson, and between the first and second there is a pretty well marked depression which is a very conspicuous feature of the topography in Virginia and Tennessee (in Pennsylvania the Kittatinny, in Virginia the Great Valley, and farther south the valley of East Tennessee).

We next come to consider the region occupied by south-eastern New York and northern New Jersey. The Green Mountains are Jersey generally considered as being prolonged south-westwardly in the and Hudson river highlands and the highland range of New Jersey. southern This latter range in New Jersey occupies a belt of country some New what over 20 miles in width on the New York line, but narrows York. down to less than half that on the Delaware. It includes no long unbroken ridges, the one which comes nearest to having this character being the Green Pond range, about 12 miles long; nor are the subordinate ridges of which it is composed in a line with each other or with their axes parallel to the direction of the main range. The highest point is Rutherford's Hill (1488 feet). The Kittatinny valley mentioned above is distinctly marked in New Jersey, where it also bears the same name. It is bounded on the north-west by a range called the Shawangunk in New York, the Blue Mountains in New Jersey, and the Kittatinny in Pennsylvania. It lies on the extreme north-western edge of New Jersey, and forms an almost unbroken straight line for about 40 miles within this State, from the Delaware Water Gap to the New York line. The straightness of this ridge and its almost level crest, from 1200 to 1800 feet in height, mark it as belonging to the peculiar topographical belt of the Appalachian system which occupies central Pennsylvania. This belt is distinctly recognizable still farther east, in the vicinity of Catskill and east of the mountains of that name, where there is a miniature group of hills, called the Little Mountains, only a mile or two in width, and but a few hundred feet in height, which are made up of rocks of the same geological age as those in the central division of the Pennsylvania Appalachians, and with the same characteristic structure.

The plateau region occupies a large portion of the State of New York. Its northern edge extends along the south side of the York Mohawk river, forming a distinctly marked escarpment (the plateau. Helderberg Mountains). Farther west, in central New York, only a few miles from the central depression through which pass the Erie Canal and the great lines of railroad connecting Albany with the west, are various heights rising 1000 feet above the surrounding plateau, and from 1600 to 2000 feet above the sea (Fenner Hill, in Madison county, 1862 feet; Ripley Hill, in Onondaga, 1968; Niles, in Cayuga, 1623; Milo Hill, in Yates, 1843; and East Hill, in Oswego, 2300). This plateau, with its extension to the south-west into Pennsylvania, forms the highlands in which rise the various branches of the Susquehanna, which traverses the entire Appalachian system, in a general direction from north-west to south-east.

In south-eastern New York there is a remarkable group of The mountains, very conspicuous from the Hudson, and apparently Catskills. quite isolated as seen from the eastern side, but which, as approached from the west, are recognized as being in intimate connexion with the plateau region of central New York. This group is known as the Catskills, of which there are two divisions,—the northern, or Catskills proper, and the southern. The Catskills proper are a massive plateau, enclosed between the Esopus and Catskill creeks—affluents of the Hudson running in a south-easterly direction, nearly parallel with each other, and at a distance of about 25 miles apart. The mountain mass thus enclosed consists essentially of two border chains running parallel with the two streams, and from 10 to 15 miles apart. The highest point of the north-eastern border is the Black Dome, 4002 feet; that of the south-eastern range, Hunter Mountain, 4038 feet. The southern group, lying south of the Esopus, the drainage of which on the west and south-west is into the Delaware river, includes Slide Mountain, the highest point of the entire Catskill group (4205 feet).

The Catskill range is, like the plateau region generally, of the Devonian and Lower Carboniferous formations. The upper 500 feet of the Slide Mountain is occupied by a cap of the Carboniferous conglomerate, the equivalent of the millstone grit, and the nearest approach to the Coal-measures in any part of New York.

From New Jersey southward the Appalachian system is very Appalachians easily separated into those divisions which have already been indicated. Its eastern border—the Atlantic slope—is an area of land in rising gradually from the sea towards the interior, to the foot of Pennsylvania the Appalachian ranges, broadening out as we follow it southward, and at the same time acquiring a greater elevation before the and mountains are reached. This gently rising area is hardly perceptible in New England, but it occupies a considerable portion of the ward. Atlantic States from New Jersey south to Florida. Its altitude Atlantic at the eastern base of the mountains is, in Pennsylvania, only slope. from 100 to 300 feet,—Lancaster and Harrisburg, which are on its western border, being respectively 350 and 320 feet. On James river, in Virginia, it is about 500 feet high (Lynchburg, 529 feet), but at the source of the Catawba it has risen to 1200 feet. This

region of comparatively low elevation is geologically, and also to a certain extent topographically, made up of two quite distinct portions. The part nearest the coast is almost flat, or with the gentlest possible slope seaward, and unbroken by any elevations worthy of notice. Beyond this belt, to the west and north-west, is another, itself almost a plain, but more undulating, rising more rapidly westward, so as to form almost a tableland at the base of the mountains, and itself diversified, in its western portion, by elevations which in places rise high enough to be called mountains. The belt nearest the shore consists of Tertiary and Cretaceous rocks having a very gentle dip seaward. These are first met with, as we proceed southward, on Raritan Bay, where the belt occupied by them is from 20 to 25 miles wide, but on reaching Philadelphia it is found to have acquired a breadth of more than 50. The stratified mass in New Jersey consists of a great number of alterations of sands, marls, and clays, from a third to half the width of the belt being occupied on the surface by the Cretaceous, and the more eastern portion being of Tertiary age. Trenton, near the western edge of this belt, is only 33 feet above the sea-level. These newer formations are of special interest on account of their fossils, and because of their great economic value. This level belt of newer rocks maintains its width through Delaware and Virginia, and attains a width of more than 100 miles in North Carolina and Georgia. Between New Jersey and North Carolina it is deeply intersected by bays, the heads of which approximately mark a change from rocks of recent age to those much lower down in the series, which make up the western portion of the Atlantic slope. This change is also most distinctly marked by an interruption to the navigability of the rivers, and it also manifests itself in the position of the cities of the Atlantic slope, most of which to the south of New York (Trenton, Philadelphia, Baltimore, Washington, Richmond, Petersburg, Raleigh, Columbia, Augusta, Milledgeville, and Montgomery) are not on the Atlantic itself, but on or very near this geological break. From Virginia southward the coast is very little indented, and most of the large towns are at a considerable distance from it. In North Carolina the slope of the coast belt—here 100 miles wide—is hardly more than 1 or 2 feet to the mile. It is occupied by nearly horizontal strata of Tertiary, overlain in considerable part by detrital accumulations of still later age, the whole consisting of loose sands, clays, marls, and gravels irregularly piled one above another. Nearly the same may be said of the continuation of this belt through South Carolina and Georgia. In the former State Columbia (between 200 and 300 feet above the sea) marks its western border. In Georgia, at the general level of the country, nearly the whole belt is Tertiary; but the underlying Cretaceous is revealed in various places where the rivers have cut deeper than usual. The heights of the cities are as follows:—Augusta, 180–180 feet; Milledgeville, 310; Macon, 334 feet.

The second or upper belt of the Atlantic slope is in large part made up of rocks which are destitute of fossils, and in regard to which it has not yet been clearly made out whether they are really stratified beds older than the lowest Silurian (Azoic or Archæan of Dana), or whether they are highly altered rocks of Palæozoic age. Over most of its area it has very distinctly the character of a plain. In Pennsylvania it is highly cultivated and densely peopled, a "country of rolling hills and gently-sloping vales, with occasional rocky dells of no great depths, and nowhere more than 600 or 700 feet above the sea-level." It is bordered on the north-west, for a portion of its extent, by a low range of elevations, known as the South Mountains, and generally considered to be the northern prolongation of the Blue Ridge of Virginia and the States farther south. The South Mountains enter Pennsylvania at the Delaware, forming a region of irregularly grouped ridges, which occupy a breadth of somewhat less than 10 miles, and which do not rise to an elevation of more than 400 to 500 feet above the valleys. These hills are made up of massive varieties of gneiss, sandstones,—recognized by the Pennsylvania Survey as being of Potsdam age,—and Lower Silurian limestones. The valleys resting on this latter rock are covered with a highly fertile soil. In Virginia the upper belt of the Atlantic slope broadens out and becomes more and more complicated in its topography. In an official report¹ this region is divided into three portions, called the Middle, Piedmont, and Blue Ridge divisions of the State. The Middle division is said to extend westward from the sea to the foot of the low broken ranges which, under the names of Kittoctin, or Kittoctan, Bull Run, Yew, Clark's, South-West, Carter's, Green, Finlady's, Buffalo, Chandler's, Smith's, &c., Mountains and Hills, extend across the State south-west from Fairfax county on the Potomac to Pittsylvania county on the North Carolina line. These broken ranges, which preserve a general parallelism with the Appalachian ranges proper, and form, as it were, the outliers of this system, are designated by Major Hotchkiss the Atlantic Coast range. This middle country is described as a moderately undulating plain, from 25 to 100 miles wide, and rising from the south-eastern border, where it is from 150 to 200 feet above the sea, to an altitude of from 300

to 500 feet along its north-western edge. It is a succession of low north-east and south-west trending ridges, the valleys between them being sometimes narrow and deep, but the ridges themselves not very prominent. The rocks are metamorphic slates and gneiss, with numerous eruptive masses in the form of dikes, and with many quartz veins, some of which contain considerable gold, although mining has not, on the whole, been successful. The Piedmont division forms a belt of from 20 to 30 miles in width, and may properly be considered as being the foothill border of the Blue Ridge itself. There is a marked tendency to the formation of a continuous valley between the broken ridges already noticed as forming the so-called Coast range and the Blue Ridge proper. In this valley lie Culpeper (400–500 feet), Fairfax (382), Charlottesville (450), Lynchburg (650), and other towns. This foothill region is described as exceedingly intricate. The coast range is succeeded, in the west, by numberless valleys of all imaginable forms, which extend across to, and far into, the Blue Ridge, to which, in point of fact, they topographically belong. Portions of the Piedmont country, however, form quite extensive plains.

The Blue Ridge with its belt of foot-hills—the Piedmont region The —forms a conspicuous feature of the topography of Virginia and the Blue States farther south. The Potomac breaks through it at Harper's Ridge. Ferry, at an elevation of 242 feet, the mountains adjacent rising about 1200 feet higher. The passes, locally known as "gaps," are numerous, and several of them are traversed by railroads. The James river intersects the Blue Ridge 706 feet above the sea. The elevation of this range is considerable, even in its northern portion, —Mount Marshall, near Front Royal and Manassas Gap, being about 3370 feet. The height as well as the breadth of the range increases rapidly as the southern line of Virginia is approached, —the Peaks of Otter, in Bedford county, near Buford's Gap, rising to 4000 feet, and Balsam Mountain, just at the North Carolina line, to 5700 feet. Here the Blue Ridge has already begun to expand into that wide and high plateau, occupying the western portion of North Carolina, in which are found the highest points of the entire Appalachian system. This elevated region is formed by a broadening out and bifurcation of the Blue Ridge, which begins near Christiansburg (2012 feet), opposite the point where the New river changes its course from a direction parallel with that of the Appalachian ranges to one at right angles to this, and breaks through that part of the system which lies north-west of the Great Valley, flowing in that direction to the Ohio. This plateau rises in North Carolina to an average height of 2500 feet, while portions of it are over 3500. It is about 150 miles in length, with a width varying from 15 to 50 miles and averaging about 30, and reaches its highest altitude (3500–4000 feet) at its narrowest part. The plateau is bordered by broken ranges; that on the south-east still continues to be called Blue Ridge; the more or less continuous line of elevations in the south-west has various names—Unaka, Smoky, Bald, and Iron being among the number. Between these exterior ridges run various spurs, with many points over 6000 feet, the culminating one being the Black Dome (6707 feet). The northern portion of this high region is drained by the head waters of the New river, but the principal drainage of the most elevated part is to the north-west, from the plateau, through gaps in the western ridges, to the Tennessee.

The geology of the Blue Ridge division of the Appalachian system is obscure and difficult. Most of the rocks are highly crystalline, but whether of Palæozoic or Azoic age is as yet undecided. These crystalline rocks are more or less intersected by ancient eruptive masses, the range and extent of which are uncertain. Flanking the Blue Ridge on the west side, and involved in the disturbances of the strata by which it has been built up, are sandstones and limestones which in Pennsylvania have been recognized as being of Lower Silurian age. These limestones seem to become more arenaceous farther south, and also to become unfossiliferous. It may be assumed, however, that the range in general is made up of rocks not newer than Lower Silurian.

To the west and north-west of the Blue Ridge division of the The Appalachian system lies the Great Valley. Its north-western Great limit in Pennsylvania is the Kittatinny Mountain, which separates Valley. it from the mountain district lying adjacent to it on that side by a very regular natural wall. The entire length of the valley in that State is about 165 miles, and its width between 10 and 11 miles. Throughout its whole extent it presents a gently undulating surface, approximating to a level plain, with here and there a belt of low hills. In Virginia the Great Valley is a very important feature, having a length of a little over 300 miles, and a quite uniform width of about 20. The mountains on its north-west side (the Kittatinny) are known by a variety of names, their northern portion being designated on some maps as the Great North Mountains. A small portion of this valley is also included within the limits of West Virginia. The drainage of the Great Valley is complicated. The north-eastern portion is the beautiful and fertile valley (about 140 miles in length) of the Shenandoah, drained by two parallel branches of that river,—a well-marked double range, 50 miles in length, dividing the Great Valley longitudinally. Through this

¹ Hotchkiss, *Virginia, a Geographical and Political Summary*, based on information obtained during the Geological Survey by Prof. W. B. Rogers in 1835–41.

range the northern branch of the Shenandoah breaks, turning at right angles to its former course and uniting with the southern branch at Manassas Gap, below which, towards the Potomac, the valley is but slightly broken by hills. South of that portion of the Great Valley drained by the Shenandoah is a region about 50 miles in length, in which are the head waters of the James. The various branches of this river, coming from north-west and south, unite at the western base of the Blue Ridge, and there break through it. The remaining portion of the valley belongs partly to the Roanoke and partly to the New or Kanawha and to the Holston. The rise of the Great Valley to the south-west is very marked, the point where the Shenandoah enters the Potomac being only 240 feet above the sea, while the head of the New river is in a region ranging from 2500 to 3000 feet. According to the official report, "the aspect of this region is singularly pleasant. The great width of the valley, the singular colouring and wavy but bold outline of the Blue Ridge, the long uniform lines of the Kittatinny Mountains and the high knobs that rise up behind them in the distance, the detached ranges that often extend for many miles in this valley, like huge lines of fortifications—all these for the outline, filled up with park-like forests, well-cultivated farms, well-built towns, and threaded by bright and abounding rivers, make this a charming and inviting region."

Middle
belt of
the Ap-
palach-
ians.

The next division of the Appalachians, which may be called the middle belt, is perhaps the most interesting and peculiar although not the most persistent portion of the system. It is not until Pennsylvania is reached that it becomes important. Its character of this division is thus indicated by H. D. Rogers in the report of the First Geological Survey of that State:—"It is a complex chain of long, narrow, very level mountain ridges, separated by long, narrow, parallel valleys. These ridges sometimes end abruptly in swelling knobs and sometimes taper off in long slender points. Their slopes are singularly uniform, being in many cases unvaried by ravine or gully for many miles; in other instances they are trenched at equal intervals with great regularity. Their crests are for the most part sharp, and they preserve an extraordinarily equable elevation, being only here and there interrupted by notches or gaps, which sometimes descend to the water-level, so as to give passage to the rivers. The whole range is the combined result of an elevation of the strata in long, slender, parallel ridges, wave-like in form, and of excessive erosion of them by water; and the present configuration of the surface is one which demonstrates that a remarkable, and as yet little understood, series of geological events has been concerned in their formation. The ridges, which are but remnants of the eroded strata, are variously arranged in groups with long narrow crests, some of which preserve a remarkable straightness for great distances, while others bend with a prolonged and regular sweep. In many instances two narrow contiguous parallel mountain crests unite at their extremities, and enclose a narrow oval valley, which with its sharp mountain sides bears not unfrequently a marked resemblance to a long slender sharp-pointed canoe." The system of ranges thus described crosses north-western Maryland, and is largely developed in Virginia, with characters in many respects resembling those which it displays farther north. It is a region of long, narrow, parallel valleys, separated by narrow, straight, and quite elevated ridges, of which no one rises greatly above the others. The number of these diminishes as we proceed in a south-westerly direction, and the belt narrows in proportion. The drainage on the extreme eastern border is into the Great Valley. The interior valleys in the northern half of the belt are traversed by streams flowing into the Potomac; the southern half is mostly drained by branches of New river. In some cases the waters flow towards a central depression in the valley, and then break through the enclosing range. The rocks are Silurian, Devonian, and Lower Carboniferous. In its north-eastern extension this division includes the anthracite region of Pennsylvania. The ridges by which the Appalachian belt proper is traversed are the result of a series of flexures of the strata, along numerous axes of elevation and depression, not complicated in Pennsylvania by extensive dislocations of the crust, or faults, either longitudinal or transverse, but gradually becoming so as we proceed towards the south-west. It is a curious fact that, in following in a south-westerly direction the Appalachian belt proper, we find that it disappears or merges in the Great Valley, which in Tennessee occupies the entire space between the Blue Ridge and the Alleghany plateau, there called the Cumberland tableland, and is fully 40 miles in width. The rocks which underlie the Great Valley are of the same geological age as those of which the Appalachian belt is composed farther north, but more closely compressed together, and complicated by great longitudinal faults, the whole area being a comparatively depressed one, and not broken by marked ridges. The true Appalachian belt is therefore limited to Pennsylvania, Virginia, and a very narrow space in Maryland, and here the system has its greatest width and most intricate and interesting topographical features, but not its highest elevations, which occur north and south of this portion, in regions of greater and more irregular disturbance, complicated by metamorphic changes and irregular

intrusions of eruptive material on a grand scale, making the task of unravelling the geological structure extremely difficult.

The most western member of the Appalachian system—the Alleghany plateau—is the one of which the geology is most easily made out, and, while its eastern border is an important topographical feature, it merges so gradually in the great central or Mississippi valley, that any definition of its limits in that direction is quite impossible. The position and elevation of this plateau region in New York have been already indicated. Farther south this tableland occupies the western portion of Pennsylvania, nearly all West Virginia, a part of Kentucky and also of Tennessee, in which latter State it is called the Cumberland tableland, or the Cumberland Mountains, since it here presents itself exceptionally with abrupt edges on the west, as well as on the east, but it is narrowed down to a width of not more than 30 or 40 miles in the northern portion of the State and of much less in the southern. The bold escarpment with which the plateau faces the east in Pennsylvania is known as the Alleghany Mountains. It is continued in Virginia, but with Alleghany much less distinctness. It is from this tableland that the waters of the Susquehanna descend to the Atlantic, crossing the entire Appalachian system in its course, while with the New river the condition of things is reversed, since this stream heads on the eastern edge of the range and flows across it in the opposite direction from that of the Susquehanna.

Since the dip of the strata in southern New York and western Pennsylvania is generally to the southward, newer rocks occupy the surface as we proceed in that direction. The Coal-measures appear soon after the line of division of these two States is passed, and it is largely with rocks of this age that the tableland is covered through the whole of its southern extension. In fact the Appalachian coalfield, as it is called, presents an almost continuous mass of coal-bearing strata, extending from northern Pennsylvania to Alabama. A part of this field, however, notably in Ohio, reaches far beyond the topographical limits of the Appalachian region.

The Appalachian tableland is, even in Pennsylvania, not entirely destitute of marked topographical features. The axes which characterize the system farther east are not wanting, but the strata are raised and depressed by gentle undulations, and not broken by precipitous ridges. Much intricacy is given to the topography, in a small way, by the streams cutting down into the soft rocks.

Before leaving the Appalachian region it will be desirable to add a few words on the belt of Mesozoic rocks occurring on the Atlantic belt of the slope, which, although not forming a prominent topographical Appalachian feature, are of much geological and palæontological interest. This belt consists chiefly of sandstones of reddish-brown colour, with which are associated shales, and occasionally, especially in the lower portion, coarser materials—conglomerates,—which are sometimes well rounded by water, but in places almost breccia-like in character. These rocks are first seen, on the north-east, in New Brunswick, in Nova Scotia, and on Prince Edward Island. In New England they are limited to the valley of the Connecticut river, with a small parallel area a little to the west of this in the towns of Southbury and Woodbury, Connecticut. The Connecticut valley Mesozoic area is about 150 miles in length, with a maximum breadth of about 14. The largest belt, however, is that extending from the west side of the Hudson river, along the south-eastern side of the South Mountains and Blue Ridge, through New Jersey, Pennsylvania, and Maryland, to about the centre of Virginia, having a maximum width of about 30 miles and a length of somewhat over 300. There are other smaller areas of the same rock in Virginia and in North Carolina,—that of the last-named State extending a short distance into South Carolina. Associated with this sandstone is a considerable amount of igneous rock, which occurs in the form of dikes and overflows, which, as the sandstone has been worn away by erosive agencies, occasionally stand out quite conspicuously, although nowhere reaching an elevation of more than a few hundred feet. Some well-known and much visited localities, such as Mount Tom and Mount Holyoke in Massachusetts, the Hanging Hills and East and West Rocks in Connecticut, and the Palisades in New York, are of this character. The fossils which the sandstones contain are not numerous, but are of much interest, and the geological age assigned to this formation by most palæontologists is the Triassic. In several localities, however, great numbers of footprints of animals occur, which were long considered to be those of birds, but are now known to belong—in considerable part, at least—to the *Reptilia*, some of which had certain features allying them to birds. The paucity of fossil remains, other than footprints, found in these rocks has rendered the working out of their true relations a matter of considerable difficulty. The latest investigations of Prof. Fontaine show that the Mesozoic areas of Virginia are separable into two quite distinct groups, an older and a newer, the floras of the two being quite different. It is in the older Mesozoic of Virginia, and in the most easterly area, near Richmond, that the coal occurs which was the first worked in the United States. The stratigraphical relations of the Mesozoic sandstones are difficult of comprehension, and have been the occasion of much discussion.

The Cordilleran System.

For convenient description, this system may be divided into the following six regions:—I. the Rocky Mountains; II. the Great Basin and the Basin ranges; III. the Northern or Columbian plateau; IV. the Southern or Colorado plateau; V. the Sierra Nevada and Cascade ranges; VI. the Pacific Coast ranges.

The Rocky Mts. I. The Rocky Mountains form the eastern border of the Cordilleran region,—a border made up of many subordinate ranges. They may be divided into two parts—the north and south trending portion, and the north-west and south-east trending portion. Between these two subdivisions there is a marked orographic break, in the form of a high plateau region, over which the Union Pacific Railroad passes at an elevation of about 8000 feet. On the north of this plateau are the Sweetwater and the much higher Wind River Mountains, which latter form the culminating region of the continent, since in them head the three great river-systems of the country,—the Missouri, the Columbia, and the Colorado.

Southern division. (A) The southern or north and south trending division is about 600 miles in length from north to south, and about 300 in breadth. Its eastern edge is extremely well marked, the ranges rising abruptly from a very gently sloping plateau. Looking at this division in the most general way, we find on its eastern edge a double range of mountains, quite distinctly marked in Colorado, or between the parallels of 38° and 41°, where they enclose a system of high plateau-like valleys, known as the North, Middle, South, and San Luis Parks, which have an elevation of from 6000 to 10,000 feet, the enclosing ranges rising 3000 to 4000 feet higher. These so-called parks are drained by the head waters of the Platte, Colorado, and Arkansas, with the exception of the San Luis Park or Valley, in which lies the upper course of the Rio Grande, whence it finds its way southward, through New Mexico, having a pretty well marked and lofty range on its eastern side, and more broken ones on the west, the two representing the Front and Park ranges of Colorado.

Colorado range. The Front or Colorado range proper, beginning as a junction at the south of the Medicine Bow range and the Laramie Hills, which are low inconspicuous ranges closing in the plateau above noticed as separating the two divisions of the Rocky Mountain system, is a broad, lofty mass, continuous from about 41° N. lat. as far as Pike's Peak, about lat. 38° 45', when it runs out into the plain. The best known points in the Rocky Mountains—Long's Peak (14,271 feet) and Pike's Peak (14,147 feet)—are in this range; both are visible from the plains, and are conspicuous landmarks. Gray's Peak (14,341 feet) is the highest point in this range; but, although on the continental divide, it is too far west to be visible from the plains. This divide, which separates the Atlantic waters from those of the Pacific, follows the Front range as far as Gray's Peak, where it is deflected westward for 20 miles to the Sawatch range, which it follows for about 75 miles. In this deflexion the divide passes between Middle and South Parks, the lowest pass in this part being that called the Tennessee (10,418 feet), which leads from the head of the Arkansas to the Grand river branch of the Colorado.

Sawatch range. The Sawatch range is one of the highest and best-marked chains in the Rocky Mountains. It lies west of the head of the Arkansas; and its dominating peaks, along the whole range, exceed 14,000 feet. The most northerly of these, the mountain of the Holy Cross (14,176 feet), was so named on account of the existence on its eastern flank of a large snow-field lying in two ravines which intersect each other at right angles, in the form of a cross, and which in summer is conspicuously visible from a great distance. The highest point is Mount Harvard (14,375 feet), and the passes range from 12,000 to 13,000 feet. The continental divide follows the Sawatch range to its southern end, in lat. 38° 20', and then runs in a south-westerly direction for about 75 miles, over a high region without any distinctly marked range. Here it turns, and, running south-easterly, follows the crest of the San Juan range, which at many points rises above 13,000 feet. This range forms the western border of the San Luis Park, and, from its north-western end, in going either north, north-west, or west the explorer finds a very elevated and exceedingly broken country, which finally merges in the plateau or "mesa" region of western Colorado. Uncompahgre Peak (14,235 feet), a magnificent isolated summit of volcanic materials, is the culminating point.

Elk Mts. West of the Sawatch range is that of the Elk Mountains, a volcanic mass of sharp pinnacles, the culminating point of which—Castle Peak—is over 14,000 feet. Between the Elk Mountains and the Uncompahgre rise the various branches which unite to form the Gunnison river.

Plateau region. The entire western portion of Colorado is a high plateau region of sedimentary rocks, of late geological age, cut deeply into by numerous streams, giving rise to cañons or ravines alternating with mesas or plateaus, the whole forming a labyrinthine succession of depressions and elevations. The mesas are sometimes so nearly eroded away that the remaining portion of the flat surface is hardly wide enough for a bridle path, while at other times there is a broad area of nearly level surface, bordered on each side by tremendous precipices. The small valleys on the streams, where there

is an area of level land large enough to be a feature in the topography, are called "parks" or "holes." The area occupied by these, in Colorado, west of the continental divide, is extremely small as compared with the whole area of the region.

When the "Parks" are spoken of in describing the Rocky Mountains, it is usually the more conspicuous ones—the North, Middle, South, and San Luis Parks—that are intended. The North Park is a tolerably level area, about 40 miles by 20, and quite walled in by high ranges rising at points above 12,000 feet. This park is a favourite resort for hunters. In it rises the North Fork of the Platte. Middle Park, which is drained by the branches of Grand river (not to be confounded with the Rio Grande), is much more broken by elevations than North Park. The continental divide surrounds it on every side excepting the west. There are but few points in this park under 7000 feet. South Park is about 40 miles in length and 15 to 20 in breadth; it is more nearly level than the North or the Middle Park, and has a higher elevation than either (about 10,000 feet at its northern end, and declining gradually southward to about 8000). The San Luis Park, or Valley, is much larger than the more northern parks, and is closed in by high mountain ranges. On its north-eastern side it has as a boundary the Sangre de Cristo range, of which the culminating point is Blanca Peak, the highest point in the Rocky Mountains (14,463 feet). The Sangre de Cristo range is almost a continuation of the Sawatch, having the same trend and similar geological characters, the two being separated by the broad depression known as Poncho Pass (about 9000 feet). The north-western portion of the San Luis Valley is closed in by the Garita Hills, which are a part of the great irregular volcanic mass continued north-westerly by the Uncompahgre and south-westerly by the San Juan range. The San Luis Valley is traversed by the Rio Grande, which enters it from the west, rising in the above-mentioned volcanic region. In the northern and wider portion of the valley the mountain streams sink or are lost by evaporation before reaching the Rio Grande, and most of this portion of the valley is sandy, and unfit for cultivation except where it can be artificially irrigated.

Proceeding westward from the San Juan range, in lat. 38°, we soon enter the plateau region which extends to the Colorado. This plateau region is bounded on the north-east by the volcanic masses of the San Juan, Uncompahgre, and Elk Mountains, at the western base of which spread the great tables or mesas of Cretaceous and Tertiary rocks, often capped by volcanic materials, and which thus already begin to exhibit the characteristic features of the plateau region. Here the principal branches of Grand river and of the Gunnison have their sources. The Grand itself rises in the Front range on the western slope of Long's Peak, while the Gunnison heads near Mount Harvard, the two uniting near the western boundary of Colorado, near 39° N. lat.

Directly west of North Park, and separated from it by the mass Uintah of the Park range, and also by a broad belt of high mesa country, range, is the Uintah range, remarkable as having an east and west trend, and thus forming a sort of connecting link between the eastern edge of the Rocky Mountain system and its western border, of which the Wahsatch range is the most strongly marked division. Starting from the eastern side of the Wahsatch, where it insculcates with it, it runs east for a distance of 150 miles, when it sinks and becomes lost in the Tertiary and Cretaceous mesas lying west of the Park range. It has the Bridger basin on the north—a continuation of the Laramie Plains,—the two together forming an important member of the orographic break between the north and south divisions of the Rocky Mountain system already indicated. The Bridger basin is underlain by rocks of Eocene age, and has an elevation of 6000 to 7000 feet, Fort Bridger itself being 6,753 feet above the sea. South of the Uintah range is the Uintah Valley, also underlain by Tertiary rocks, and forming the north-westernmost division of the Colorado plateau region. The Uintah range itself is of very simple geological structure, being a low flattened anticlinal, complicated by one or more faults on the northern edge. The Tertiary and Cretaceous strata have been so much eroded away on the higher portion of the flattened arch that the chief rock exposed in the body of the range is the underlying Carboniferous. The highest points, as given by the Fortieth Parallel Survey, are Gilbert's Peak (13,687), Tokewanna (13,458), and Wilson's Peak (13,235 feet). The southern slope of this range is drained by the affluents of Green river, which unites with the Grand, about 175 miles farther south, to form the Colorado.

The Wahsatch range is one of the most conspicuous of the Wahsatch Rocky Mountain system, and, as it borders the Great Basin on its range, eastern side, it may properly be considered as forming the western limit of the Rocky Mountain southern division of the Cordilleran system. This range has a nearly north and south trend, rising with a bold escarpment to a height of nearly 12,000 feet in the portion of the range just east of Salt Lake City, but falling off gradually towards the north and not being recognizable as a distinct range beyond Bear river. This stream rises on the northern slope of the Uintah range, in nearly the same latitude as that of

Salt Lake City, then flows northward for more than 100 miles, to lat. 42° 40', when it turns and follows an almost exactly opposite course, finding its way round the north end of the Wahsatch range and emptying into Great Salt Lake. In the loop thus made by Bear river is the Bear River range, in which North Logan Peak rises to 10,004 feet, and others are of nearly equal altitude. The whole of the Wahsatch region—the range of that name as well as the parallel ranges and spurs on the east—is one of difficult and complicated topography. It forms the connexion between the north and south divisions of the Rocky Mountains, and connects by spurs and irregular lines of elevation with the Wind River range, the range of the Tetons, and the Snake River Mountains.

Although Bear river runs for more than a hundred miles in a northerly direction before crossing the Wahsatch range, the Weber river, which rises in the Uintah range, within three or four miles of the head of Bear river, runs with a pretty direct north-westerly course across that range, breaking through it where it is from 8000 to 9000 feet in elevation, and affording an easy route for the railroad from the Bridger and Green river basin to Salt Lake.

(B) The northern division of the Rocky Mountains has been much less fully explored than the southern. It also is made up of a large number of ranges, having a general though by no means uniform north-west south-east trend. As a whole, this division is lower and less impressive from the grandeur of the masses than the southern; and as we advance north-westerly we find more monotony in the scenery, more uniformity in the height of the ranges, and an almost entire absence of dominating peaks. Striking exceptions to this condition are offered by the Wind River range and the Yellowstone geyser region.

The Northern Pacific Railroad, by which access is had from the east to this portion of the Cordilleras, strikes across the plains from the western end of Lake Superior, directly west to the Missouri, which it crosses in 101° W. long., at Bismarck, near the centre of Dakota. From this crossing it runs in almost a straight line to the Yellowstone river, which it follows for a distance of 340 miles. It then crosses to the Missouri at Gallatin, and follows that stream to near Helena, a distance of about 100 miles. From here the ascent of the main divide of the Rocky Mountains is made by way of Mullan's Pass, the summit being crossed by a tunnel 3850 feet long, at an elevation of 5548 feet. Thence the line follows Hell-Gate river, the Missoula, and Clarke's Fork, to Lake Pend d'Oreilles (2059 feet), which it curves round on the north, and then strikes directly south-west to the junction of Snake river with the main Columbia.

The Rocky Mountains, in their north-western portion in Montana and Idaho, are more irregular in their development than they are farther south. There is, however, a similar tendency in both regions to the formation of those mountain-encircled valleys which are so generally known in this region as "parks," although not infrequently called "prairies." These parks are mostly destitute of timber, excepting the cotton-woods along the banks of the streams. The mountains are more or less covered with coniferous trees, not of great size, but sufficiently large for ordinary building purposes. As the ranges themselves are lower than in Colorado and in the southern division generally, so the high enclosed valleys are also proportionally lower. Portions of them have a soil suitable for cultivation; other portions are covered with bunch grass and well adapted for grazing. There is considerable uncertainty in the nomenclature of the various individual ranges. The name Bitter Root is most frequently given to an important range, which in a portion of its course forms the main divide between the Missouri and the Columbia, but which, farther to the north-west, separates the waters tributary to the Snake from those which unite to form the Clarke's Fork. The Lapwai and Cœur d'Alène ranges lie west and north-west of the Bitter Root Mountains, and unite the Rocky Mountains with the Blue Mountains, an important, but little-known group of ranges occupying a considerable portion of the region lying west of Snake river. There are also various groups of mountains, more or less isolated in position, and lying to the east of the main range of the Rocky Mountains in this portion of their extension. The Crazy Mountains form an isolated group immediately north of the Yellowstone river. They occupy an area about 40 miles long and 15 wide; the highest point is Crazy Peak (11,178 feet), and there are numerous others approaching 11,000 feet. The mass is formed by immense outbursts of volcanic rocks through horizontally lying strata consisting of sandstones and shales of Cretaceous age. The Judith Mountains form another more or less isolated group farther north-east, in 109°–110° W. long. To the south-east, again, are the Big Horn Mountains, an extensive range forming an advance guard, as it were, of the main chain, between 48° and 46° N. lat. Still farther east, and in entire isolation from the main range, is the large and important group known as the Black Hills, in 103° to 105° W. long., embracing a region which has lately become of considerable importance on account of its mineral wealth. This group covers an area of an irregularly oval shape, about 120 miles in length and from 40 to 50 in width; the average elevation is from 2000 to 3000 feet above

the surrounding country; but the highest point—Mount Harney—reaches 9700 feet. Deadwood, the principal mining settlement, has an elevation of 4630 feet. The geological structure of this range is comparatively simple, and typical of that of a very considerable portion of the Rocky Mountains, especially of the ranges of the northern division. The central or axial mass is of an oval form, about 70 miles in length by 40 broad, and is made up of crystalline rocks,—granitic, gneissoid, and schistose in character. The sedimentary rocks rest upon it unconformably, folded like a mantle around its base, and everywhere dipping from it, at a higher angle near the axial mass, and at a lesser one as we recede from it. The lowest fossiliferous rock is the Potsdam sandstone, from 200 to 300 feet in thickness. On this rests conformably a series of beds of Carboniferous age, 600 to 700 feet in thickness, and this group is succeeded by the series of deep-red sandy gypsiferous strata, the "Red Beds" of the Rocky Mountain geologists, a very conspicuous feature of the geology through a large portion of this region, and the more so because often eroded into peculiar fantastic and picturesque forms. These beds are considered to be of Triassic age. In the Black Hills their total thickness varies from 300 to 400 feet. Above the Red Beds lies the Jurassic, which here has a quite uniform character, and is made up of grey or ash-coloured marls, marly limestones, and soft sandstones. The thickness of this group in the central region of the Black Hills is about 200 feet, increasing to the north, and attaining in Belle Fourche Valley a maximum of 600 feet. In the Wind River range the Jurassic is more largely developed, and farther to the south and south-west, through the Rocky Mountains and in the ranges south of the Great Basin, it is still thicker. Above the Triassic and Jurassic, and conformable with them, are the various members of the Cretaceous series, so largely developed in this region, varying in lithological character, the upper 600 feet composed of soft, easily eroded materials, and containing many characteristic Cretaceous fossils. The position of these various groups of strata, some quite hard and others very soft, wrapped concentrically around the axial mass, and cut through by a radial drainage, has given rise to an interesting topography, easily understood from its simplicity, and little obscured by any covering of forest vegetation. A remarkable feature of the landscape, on the western bank of the Belle Fourche, is the Bear Lodge, or Devil's Tower, "a great rectangular obelisk of trachyte, with a columnar structure, giving it a vertically striated appearance," rising 625 feet from its base, the summit being entirely inaccessible.

II. The Great Basin is the name now given to a region embracing The an area of about 225,000 square miles, and having no drainage Great to the sea. Its shape is roughly triangular, the apex of the triangle Basin. being near the mouth of the Colorado river, and its base extending in an irregular line, approximately east and west in direction, from near the north-eastern corner of California to a point on the northern slope of the Uintah range, where, as already mentioned, Bear river has its source. The length of the east side of the triangle thus designated is approximately 600 miles. From the northern side or base the drainage is into Snake river; on the south-eastern side rise various branches of the Colorado; and the south-western is very distinctly marked, for the greater part of its length, by the crest of the Sierra Nevada.

The Great Basin is an elevated plateau, traversed by numerous Its topo- ranges of mountains, having a general north and south trend, and graphy. a very considerable elevation above the intervening valleys. While there is a marked tendency in these ranges to isolation from each other, and to separation by deep and persistent valleys, there is still so much inoculation of one range with another, and so much irregularity in their development, that it is extremely difficult to define their number or to group them. Starting from the crest of the Sierra Nevada, at a point west of Pyramid Lake, and going in a direction a little north of east to Salt Lake, the traveller would cross about twenty mountain chains, mostly very distinctly marked, and separated by deep valleys of from 4 to 20 miles in width. The height of the plateau from which these chains rise is greatest in its central portion, and it declines east and west and also towards the south, where considerable areas are actually below the level of the sea. The most important centres towards which the drainage converges are Salt Lake, about 4250 feet above the sea, and the sink of the Humboldt and Carson, very nearly at the same elevation. The head of the Humboldt river is near Cedar Pass (6263 feet), about 100 miles west of Salt Lake. This river therefore marks a distinct line of depression near the northern edge of the Great Basin, and in going south from this we rise in the various valleys to heights of from 5000 to 7000 feet. The Humboldt Sink not only receives the surplus drainage of the northern portion of the Basin, but is on the same level, and after a wet season in actual continuous connexion, with the Carson Sink, into which quite an extensive portion of the eastern slope of the Sierra Nevada is drained. Throughout the Great Basin the valleys between the ranges are themselves usually sinks, the lower portion being frequently occupied by bodies of water which vary in size according to the atmospheric precipitation of the preceding winter, and in many cases are hardly more

than saline incrustations resting upon a more or less muddy bottom. In general the valleys are nearly bare of vegetation in their lower portions; higher up they are covered with a growth of desert shrubs. There are, in occasional favoured localities, small sedge-grass meadows. There is a rapid falling off in elevation of the Basin region towards its south-western corner, and here portions are below the sea-level. Death Valley, the sink of the Armagosa river, is one of these depressed regions, and along the line of the Southern Pacific Railroad is another depression, a little over 60 miles in length, the lowest portion of which is 263 feet below the level of the sea. Of the ranges traversing the Great Basin, with a trend approximately north and south, some are short and inconspicuous, while others maintain an almost unbroken crest for 100 miles or more. Their parallelism in certain portions of the Basin is very striking. The loftiest range is that called the East Humboldt—or more frequently simply the Humboldt; this rises about the middle of the Basin, its southern end being in $115^{\circ} 30' W.$ long., and runs north-north-east for about 100 miles to near the head of the Humboldt river. At the north end of this range is Mount Bonpland (11,321 feet), the culminating point of the Basin ranges. The Pah-Ute range, about 150 miles west of the Humboldt, is another very persistent line of elevations, although rather irregular in trend, and not very high. The West Humboldt range is also a conspicuous one near the western side of the Basin; its culminating point is Star Peak (9925 feet). The mountain ranges of the Basin are characterized by the almost entire absence of forest vegetation, trees being abundant only in their higher portions in the deeply hidden cañons. The rocks are everywhere exposed along the ridges and flanks. The valleys are deeply filled with detrital materials, which rise sometimes along the flanks of the ranges to a very considerable height, with a steep but gradually diminishing slope, indicating the former greater energy of erosive agencies.

Geology
of the
Great
Basin.

The Great Basin is an interesting field for the geologist. The most important feature is the entire absence of the marine Cretaceous and Tertiary formations, which play such an important part in the Rocky Mountain division. With the exception of the late freshwater Tertiary of the Humboldt river and some of the areas farther west, and of the post-Pliocene detrital accumulations of the valleys, there is nothing more recent than Jurassic, and very little of this, the most recent really important fossiliferous formation being the Alpine Trias. The stratigraphical relations of the formations, especially with reference to the building-up of these ranges, are mostly simple, as in the Appalachian and Jura ranges, or even simpler still. Some ranges are simple monoclinals, others anticlinals, and others again synclinals, or a combination of two or more of these forms of structure. They are rarely or never closely compressed and only moderately faulted. The striking peculiarities of Appalachian erosion, due in large part to the repetitions of hard and soft strata, are not to be found as important elements in the Great Basin topography. The Basin ranges differ, however, in a marked degree from those of the Appalachian and Jura in the almost constant presence, and sometimes overwhelming importance, of the volcanic masses throughout the whole region. In some instances these formations make up the whole range; or, at least, the whole interior skeleton of older rocks, if such exist, is concealed by them; in other cases the eruptive materials have been poured forth along the base of the uplift, and there form great plateau-like masses; or they have issued from the summit of the range and spread themselves there in sheets, or flowed down the flanks of the central mass. In this respect the Basin ranges maintain a unity with the other portions of the Cordilleran system, throughout which the exhibition of the results of volcanic energy during the later geological periods is everywhere manifested on a scale perhaps unequalled elsewhere.

Northern
plateau.

III. The Northern or Columbian plateau embraces the region enclosed between the northern extension of the Rocky Mountains on the east and the Cascade range on the west. It is the basin of the Columbia river, which drains it by means of two principal branches, one of which retains the name Columbia to its source beyond the boundary of the United States, while the other, originally named the Lewis, is now almost universally known as the Snake river. The Columbia itself forks near the boundary line, the main river coming down from the north, and being joined by Clarke's Fork from the south-east. The Columbia and the Snake, after uniting, flow westward for about 100 miles, before breaking through the Cascade range. This area is the portion of the United States of which we have the least topographical knowledge, and therefore only its more striking features can be indicated. The north-westerly trend of the northern division of the Rocky Mountains reduces the width of the Cordilleran system as we go north, since the Cascade range remains unchanged in its direction from the southern line of Oregon to the northern boundary of the country. The area between the two systems is more or less completely filled with mountains of which little is definitely known. Of these there are two principal groups, the Blue and Salmon River ranges, of which the former lies in the angle made by the Snake in its northerly course before reaching the Columbia, while the latter forms an

intricate mass, extending from the westernmost ridge of the Rocky Mountain system westward towards the Snake.

The Columbia river rises only 100 miles north of the boundary Columbia line, but runs nearly 200 miles farther in a north-westerly direction river, before turning to go south again in a course nearly parallel to that it had before. The Okanogan joins it about 70 miles south of the boundary line and from here the course of the Columbia is southerly, parallel with the Cascade range for about 160 miles to the Great Bend, when the river takes a nearly westerly direction, which it keeps until, after having passed through the range, it reaches the Pacific. All the region lying north and west of the river and between that and the Cascade range is mountainous. The topography is very irregular, but there is a general tendency to a north and south trend, which is still more marked in the region between the Columbia and Clarke's Fork. Here the ranges on each side of the north-flowing Colville rise to from 5000 to 7000 feet in height.

South of the Columbia is a vast area, extending to the edge of The Great Basin, and enclosed between the Rocky and Cascade volcanic Mountains, of which the main feature is that a very large portion plateau. is deeply covered by volcanic formations, which here extend over a larger continuous area than anywhere else in the world, with the possible exception of the Deccan in India. This volcanic plateau-like region extends northward into British Columbia and south to near the line of the Central Pacific Railroad in Nevada, from which its dark and frowning walls are visible; it extends up Snake river valley to the base of the Rocky Mountains, and south-west, through California, into the valley of the Sacramento. Along the Columbia river it unites with the great volcanic mass on which Hood, Adams, and St Helens are built up, and still farther north it merges in the eruptive accumulations which reach their greatest elevation and grandeur in Mount Rainier. These lava masses lie in nearly horizontal beds of varying thickness, interesting in their geological relations, but extremely monotonous from the scenographic point of view. They are often cut deeply into by the streams which in some places have sunk their beds below the general level of the country to the depth of more than 500 feet. These are not infrequently precipitated over the edges of the volcanic masses in cataracts, which sometimes are extremely picturesque. The falls of the Pelouse river are striking, but those of the Snake river known as the Shoshone Falls are by far the finest, and among the waterfalls of the United States perhaps come next to Niagara in grandeur. On the volcanic plateau are occasional cones, occurring singly or in groups, but much the larger portion of the overflows seem to have taken place in the form of massive eruptions, by which wide areas were covered very uniformly with lava, and on these nearly horizontal masses the cones have been built up during the dying out of the eruptive agencies. The volcanic rocks cover an area, about the Columbia and its branches, east of the Cascade range, which may be safely estimated at fully 100,000 square miles,—perhaps at considerably more. A large portion of this area was once occupied by bodies of fresh water, the deposits from which, in the form of sands and clays, have been exposed by erosion in various places, and are found to be rich in remains of land and aquatic animals, mostly of late Tertiary age. A considerable number of lakes still occupy portions of the surface, and an extensive group of these, some of which are of large size, although shallow, occupies a corner of Oregon, and an adjacent part of California, east of the Cascade range. Much of the surface is dry and barren. The valleys along the river courses are in many places well adapted for cultivation; but these fertile areas are of comparatively small extent. The mountain ranges around the bases and over the lower portions of which the volcanic materials have been deposited appear to resemble, lithologically and geologically, the rocks of the Sierra Nevada. In the Owyhee Mountains there is a central core of granite, on which rest metamorphic slates and sandstones, forming a belt 20 miles wide on the south-western side of the range, and half as much on the other side. In the granitic axis are numerous veins of quartz, carrying free gold and ores of silver. With the exception of occasional hot springs, volcanic activity seems to be extinct, or at least to have been for some time dormant. There seems to have been, about the close of the Tertiary epoch, a period of extraordinary volcanic activity throughout the Sierra Nevada and Cascade ranges, and over a vast extent of country to the east. It does not appear, however, that there has been during the post-Tertiary times any eruption of fluid lava which would harden into solid rock on cooling.

IV. Enclosed between the ranges of the Rocky Mountains on the Colorado east and the Sierra Nevada on the west there are—as has been seen plateau—numerous high plateau-like districts, the beds of old freshwater lakes, some of which were of large dimensions. The strata deposited at the bottom of these lakes have been cut into by erosive agencies in numerous places, so that the geological structure stands fully revealed, while the wealth of organic remains which they contain has made these old lake-beds wonderfully attractive to palæontologists. The drainage, desiccation, and subsequent erosion of these areas have given rise to a remarkable type of scenery, to which the name of

Mauvaisis Terres was applied by the fur-hunters. These Bad Lands, which lie south and south-west of the Missouri and along its tributaries coming in from that direction, may be considered as the precursors and representatives of lands which, from the agricultural and business point of view, are bad enough, but which to the geologist and lover of the picturesque are in the highest degree good, and which are perhaps, on the whole, more striking than anything which the continent elsewhere exhibits. The essential features of their unique and striking type of scenery (of which the Grand Cañon of the Colorado is the grandest and most complete example) are these:—a heavy mass of stratified materials, several thousand feet in thickness, and covering many thousand square miles, has been cut into and eroded away, so as to give rise to a labyrinthine series of gorges, or “cañons,” having a depth of from 1000 to 5000 feet, the walls of which are almost always extremely precipitous and in places perpendicular, and are by no means flat surfaces, but are worn and sculptured into forms almost always peculiar and striking, and often fantastic in the highest degree. And to a variety and complexity of form which seem to find a parallel nowhere on the earth is added the attraction of colour, the various groups of strata forming the cañon walls presenting a gay adornment of tints of red, yellow, purple, brown, and grey, the depth and brilliancy of which surpass belief.

The region in which these wonderfully picturesque forms of landscape occur lies to the south and east of the Great Basin, between Great Salt Lake and the Colorado, to the west of the Green river branch of that river, extending west, with a gradual disappearance of its characteristic features, to near the border line of California. The Uintah Mountains may with convenience, although somewhat arbitrarily, be taken as the northern limit. But, in point of fact, the characteristic type of scenery begins to be developed in Colorado, where the Book or Roan plateau, which rises to a height of 9000 feet, is deeply cut into by the White river in the north and the Grand river in the south.

The south-westernmost portion of the region, or that portion which includes the Grand Cañon and its branches, has a length from north-east to south-west of about 180 miles and a breadth in the opposite direction of about 125 miles. On the west it has as its boundary a grand escarpment which marks the change from “the calm repose of the strata with horizontal surfaces to the turmoil of flexed beds and jagged mountain crests” exhibited in the Sierra and the adjacent ranges on the south-east, in the deserts of southern California. The transition from one type of geological structure to the other on that side is said to be so abrupt that one “might almost hurl a stone from one region to the other.” On the north the Grand Cañon receives the drainage of four distinct plateaus, the Sheavvits, Uinkaret, Kanab, and Kaibab, east of which lies a fifth (the Paria), which drains into Marble Cañon,—the prelude to the Grand Cañon. The Paria plateau differs from the others in that it lies at a lower level and is covered mainly by Triassic rocks, while the others present an almost unbroken expanse of Carboniferous strata. The southern boundary of the Grand Cañon district is a continuation of the western. The same great escarpment which overlooks the Sierra to the west stretches southward across the Colorado, preserving the same features for 30 or 40 miles. Slowly changing its course, it follows a south-easterly course through eastern Arizona, where its edge is known as the Mogollon Mountains. Passing this line to the south-west, the country descends at once from the horizontal platform into a lower country having apparently similar geological features to those presented in the Sierra country to the west. The following are some of the more interesting facts connected with the form and structure of the plateaus making up the Grand Cañon district on the north of the Colorado. The Sheavvits has on its western side the so-called “Great Wash,” a broad and deep valley to the north of the Colorado. The great escarpment of this plateau is a fault or break, along the course of which the country to the east has been raised several thousand feet. The Uinkaret plateau, which adjoins the Sheavvits on the east, is separated from it geologically by another great fault, the Hurricane Ledge, which marks a rise of the region to the east to the amount of 1600 or 1800 feet, and which is prolonged far to the north. On this plateau are numerous cones and flows of basaltic lava, some of which appear to be of very recent origin. Under some of these are beds of Permian age, lying over the Carboniferous, and preserved from erosion by the harder eruptive material with which they are capped. Another short fault separates the Uinkaret from the Kanab plateau on the east. The Kanab is the broadest of the four plateaus, and has a grand side cañon cutting deeply into it, and running to the Colorado. The Kaibab plateau comes next on the east. Flat on the summit, and terminated by lofty battlements upon its eastern and western sides, this is much higher than the other plateaus to the west, being from 7500 to 9300 feet above the sea-level. Its surface is covered in part with forests, grassy parks intervening which in summer are gay with flowers of rare beauty and luxuriance. The total length of this plateau is about 90 miles, and its maximum width about 35. It is a block of ground raised by displacement

between two great faults. Farther east and at a much lower altitude is the Paria plateau, “a terrace of Triassic strata scored with a labyrinth of cañons;” and farther north-east, again, is the Kaiparowits, which is nearly equal to the Kaibab both in size and altitude; this is composed of strata of Lower and Middle Cretaceous age. Still farther north is a succession of plateaus, separated from each other by lines of dislocation, which, however, gradually close and become less conspicuous in this direction, the topographical features of the region being dependent chiefly for their existence on simple erosion, with the frequent occurrence of curious volcanic formations, and not so much on bodily uplift and depression of great masses of strata by faulting. On the southern side of the Colorado is another vast expanse of plateau land, underlain by nearly horizontal strata, which, with one unimportant exception, are not deeply scored with cañons as is the region to the north. “Low mesas, gently rolling, and usually clad with an ample growth of pine, piñon, and cedar, broad and shallow valleys, yellow with sand or grey with sage, repeat themselves over the entire area. The altitude is greater than that of the plateaus north of the Colorado, except the Kaibab, being on an average not far from 7000 to 7500 feet. From such commanding points as give an overlook of this region one lonely butte is always visible, and even conspicuous, by reason of its isolation. It stands about 20 miles south of the Kaibab division of the Grand Cañon, and is named the Red Butte. It consists of Permian strata lying like a cameo upon the general platform of Carboniferous beds. The nearest remnant of similar beds is many miles away. The butte owes its preservation to a mantle of basalt which came to the surface near the centre of its summit. . . . Fifty or sixty miles south of the river rise the San Francisco Mountains. They are all volcanoes, and four of them are of large dimensions; the largest—San Francisco Mountain, nearly 13,000 feet high—might be classed among the largest volcanic piles of the west. Around these four masses are scattered many cones, and the lavas which emanate from them have sheeted over a large area.” The length of the Grand Cañon of the Colorado, following the meanderings of the river along the middle of its water-surface, is about 220 miles. Where the cañon is narrowest it is five miles across from the edge of one wall to the edge of the other. The general depth is 2000 feet; but in the centre is a portion 3000 feet deeper, having a width about equal to its depth. The Kaibab division, or that part which has the plateau of that name on the north, is the most stupendous portion of the Cañon, a thousand feet deeper than any other, and far more diversified and complex in its structure.

The peculiar interest of the topography of this region is due in part to the manner in which great blocks of strata have been raised or depressed between long faults, which have given rise to differences of level amounting to thousands of feet, and in part to the extraordinary amount of erosion which the region has undergone, first over its whole surface where not protected by overlying masses of harder volcanic material, and, later, in the channels of the streams, which channels have been gradually growing narrower with the lapse of time, the streams diminishing in volume, until during the present epoch they have either shrunk to nothing or have become absolutely insignificant in comparison with what they were in later Tertiary times. In fact, we have in this region the best possible illustration of the progress and effect of that stupendous desiccation of the climate which has long been manifesting itself all over the world, and of which the results may easily be traced far back in geological history. The contrast between the plateau region south and south-east of the Great Basin and that lying to the north—between the region of the Colorado and that of the Columbia—is a most striking one. In the north the volcanic outflows have filled the depressions in the corrugated and folded strata, covering over the whole of the lower portions of the region, from which the older mountain ranges project like islands from the great congealed sea of lava. The rivers could not subsequently cut very deep into these overflows, because the material is so hard and the general level of the region so low. In the Colorado region, on the other hand, the strata have not been crumpled, folded, and metamorphosed, but raised *en masse* to a high elevation, and not hardened so as effectually to resist erosion; and, possessing just enough variety of lithological character to prevent uniformity of wearing away and give complexity to the resulting forms, they have, under the simple influence of eroding agencies, assumed the wonderful condition in which we now behold them. Here, too, volcanic agencies have been active; but the molten material has been poured out from orifices at a great elevation, and has built up cones, some of which are of nearly as grand dimensions as the mightiest of the Sierra Nevada and Cascade range; but the valleys and lower regions have not been filled up by them, nor have there been in the southern plateau region any such enormous overflows as those which characterize the northern volcanic district.

V. The Sierra Nevada may without hesitation be called the most Sierra important and interesting member of the Cordilleran system, not Nevada. only as a long and elevated mountain chain,—on the whole the

most conspicuous within the limits of the United States,—but also for its minerals, its climate, its peculiar geological features, its remarkable forests, its scenery, and the comparative density of the population along its western flank. Its importance and interest are still farther enhanced if (as on the whole seems a reasonable thing to do) we consider the Cascade range as being a continuation. The Sierra Nevada proper forms the western edge of the widest and highest portion of the Cordilleras, or that portion which lies east of the State of California. It is especially conspicuous from the western side, because on this side it falls nearly to the level of the sea, while on the other side it sinks only to the general plateau level. It does not, however, border the Pacific directly, since there is, all along its course, a lower system of mountains, rising directly from the coast—the so-called Coast ranges. With these the Sierra Nevada and the Cascade range are so inoculated in certain portions of their extent that a topographical separation of them is impossible, but for a considerable distance both the Sierra and the Cascade range are distinctly separated from the Coast ranges by broad low valleys, the most extensive of these being the Great Valley of California (for which, as well as for the more important features of the Californian Sierra, the reader is referred to *Ency. Brit.*, vol. iv. pp. 696-8). The Sierra Nevada has been already shown to be made up of a core of eruptive granite flanked by rocks of Mesozoic age; the development of these Mesozoic rocks increases towards the north, and in the region lying along the western declivity of the chain, in the central portions of the State, forms the auriferous belt of the Sierra. The gold-producing detrital deposits, formerly so extensively worked, are gravels of Tertiary age covered more or less completely by volcanic materials, which not unfrequently attain a thickness of several hundred feet. As in other portions of the Cordilleran region, the presence of eruptive rocks of Tertiary and post-Tertiary age is a fact of great importance. The volcanic materials in question are seen in places in large masses on almost the very highest portion of the Sierra, in its southern extension, in a region where there is very little of this material lower down on the flanks of the range, and where there are no slates and no mining or washing for gold of any importance. Just south of the Mount Whitney group, where the Sierra rapidly falls off in height between the two ranges of which the system is here comprised, there is a region—the valley of the Kern river—in which occur several volcanic cones, which have a very recent look, but which are not known to have been in eruption since the advent of the whites. This region, however, for several years in succession—from 1870 onwards, and perhaps from an earlier date—appears, on good evidence, to have been repeatedly and violently disturbed by earthquakes; and this seems also to have been the portion of the Sierra which was most affected by the great earthquake of March 28, 1872. Midway in Owen's Valley, on the east side of the Sierra, beginning about 30 miles north of Lone Pine, where this earthquake was most disastrous in its effects, there is a region of volcanic cones and lava-flows, by which the river is crowded over against the Inyo range, at the foot of which it has only just room to flow. These cones are seemingly as perfect as they ever were; and the flows of basalt have spread themselves out over the sage-brush slope in a manner indicative of a very recent date for their out-breaking. Yet all seem now to be entirely dormant. Even solfataric action is almost (if not quite) exclusively manifested at the present time at or near the summits of the highest volcanic cones of the Sierra and the Cascade range. Farther north more and more volcanic materials cover the western flank of the range; and from about 39° 30' N. lat. much the larger portion of the older rocks is overlain and concealed by modern eruptive materials, through which the streams have worn channels, often of great depth, from the sides of which access is given to the auriferous gravels occupying the bottoms of the channels of the old Tertiary but now buried river-systems. In Lassen's Peak, in 40° 30' N. lat., we have the first exhibition of the isolated volcanic cone rising high above the adjacent country, which makes so prominent a feature of the range farther north in California and through Oregon and Washington Territory. This volcanic mass is 10,537 feet in height, and there are abundant signs of recent volcanic activity on and near it. There are, in this vicinity, several localities where hot springs occur, and where the rock has been so softened by solfataric action as to have given rise to mud lakes, in which jets of hot water and mud are sometimes thrown to a height of several feet. One of these places, about 8 miles from the summit of the peak, is 5976 feet above the sea, and there is here a pool of hot water 600 feet long by 300 broad, in the midst of which miniature mud volcanoes are being constantly formed. There are no such striking indications of dormant volcanic activity as are seen in the vicinity of Lassen's Peak anywhere to the southward along the crest and flanks of the Sierra. Neither is it known that there has been anything which could be properly called an eruption, whether of lava or ashes, since the region was first visited by the whites, either from Lassen's Peak or from the much grander volcano to which the name of Shasta is given. At Lassen's Peak a great change takes place in the character of the range, which is here broken through

transversely by a great fault, to the south of which we have the high ranges and deep cañons often cut down through the volcanic strata, and sunk deeply into the underlying metamorphic rocks, while to the north is a great depression, comparatively level, and exclusively occupied by volcanic rocks, which stretch off to the north and north-east, in almost unbroken continuance, for many hundred miles, forming a portion of the northern plateau region already described. Seventy miles north-west of Lassen's Peak rises Mount Shasta (14,440 feet), standing in remarkable isolation on a base between 10,000 and 11,000 feet lower than its summit. There are indications of former volcanic activity near the summit, but they are not so marked as those on and near Lassen's Peak. There is a flat area about 400 feet below the summit, on one side of which are several orifices from which steam and sulphurous gases were constantly escaping at the time of the present writer's ascent of the mountain (1862).

North of Mount Shasta the mountain mass now called the Cascade range maintains characters similar to those which it has between Lassen's Peak and Shasta for a distance of fully 500 miles, or until we have passed the northern boundary of the United States. The principal continuous ridge is comparatively low, and on it at irregular intervals rise great volcanic cones, differing considerably from each other in elevation, but all much higher than the surrounding plateau-like base on which they are built up. Unfortunately no portion of the Cascade range has as yet been topographically surveyed. From Mount Shasta northwards there are several prominent peaks, which are apparently volcanic, but which have not the conical form, while others exhibit this peculiar feature in a high degree of perfection. Mount Pitt (9718 feet) is a well-defined cone, about 75 miles north of Shasta. Mount Jefferson, about 150 miles still farther north, is of a similar character; and between Pitt and Jefferson are various prominent peaks, especially the highly picturesque group of five sharp points, known as the Three Sisters, only three of them being visible from the Willamette Valley. All through this portion of the range evidences of comparatively recent volcanic action are present, in the form of regular craters and outflows of lava. Somewhat less than 100 miles north of Mount Jefferson is the grand break made in the Cascade range by the Columbia river, which has cut entirely through the volcanic mass, down almost to the level of the sea,—the Dalles, on the eastern side of the range, having an elevation of only about 100 feet. At the Dalles—so named on account of the great, broad, flat plates or sheets of lava which are there well exhibited on and near the river—is the beginning, in this direction, of the volcanic plateau of the Columbia. Near this point rise three of the best-defined volcanic cones of the range, two—Mount Adams and Mount St Helens—on the north side of the river, and one—Mount Hood—on the south. The last-named has been found by barometric measurement to be 11,225 feet; the other two seem to be of nearly equal height (about 10,500 feet). Mount Rainier (14,444 feet)—about 75 miles north of the Columbia river—is rivalled in the whole of the Cascade range by Shasta only. The views of Rainier from Puget Sound are magnificent. It is much less accessible than Shasta, as it lies in the midst of a dense forest, far from roads; it is also very much more deeply covered with snow and ice. Still farther north than Rainier, and near the boundary line of the United States, is Mount Baker (10,755 feet), a prominent object in the grand panoramic view from Victoria, Vancouver Island. While evidences of comparatively recent volcanic action are so conspicuous all along the range from Lassen's Peak north to Mount Baker, it is not easy to reconcile the conflicting evidence with regard to the present condition of the eruptive agencies. The present writer, during several years of exploration, found no evidence whatever of any recent outflow of melted lava, such as would harden into a solid rock on cooling, in any part of the Sierra Nevada or the Cascade range. The eruptive rocks of these ranges are mainly andesites; but the last outflow of molten rock appears to have been basaltic in character. This is certainly true for the Sierra Nevada, and probably so for the Cascade range. Under the basalt we find, in the buried sedimentary strata, abundant remains of vegetation, pronounced by competent authority to be Pliocene in age, with a few species intermingled which have a decidedly Miocene character. The animal remains found under the basaltic lava are all of extinct species, with the single exception of man, whose bones or handiwork have been repeatedly taken from strata occupying this geological position. The age of the sedimentary beds under the basalt is therefore Tertiary, from the combined evidence of both plants and animals. There is no evidence that fragmental lava—ashes, cinders, and the like—has been emitted from any one of the volcanic cones of the Sierra Nevada since the region became known to the whites; but there is abundant evidence to this effect in regard to some of the high points in the Cascade range. Mount Baker seems to have furnished the most unquestionable proof of activity in recent times. The first known eruption of this volcano appears to have taken place in 1843. In at least three later instances Mount Baker has been seen in eruption by men of un-

questionable authority,—in 1854, 1858, and 1870. Smoke and steam are said to have been frequently seen rising from the summit of St Helens. It is not easy to reconcile the statements which have been made in regard to the activity of Mount Hood. Eruptions of this mountain have been reported as having taken place; but the present writer in 1867 made inquiries of persons having it in full view, without being able to procure satisfactory evidence of any activity similar to that of Baker and St Helens, at least within the preceding twenty or thirty years. There is no evidence of any similar activity of Mount Rainier; but, according to Stevens and Van Trump, who were the first to reach the summit of this mighty cone, jets of steam issue from the crater at the summit in sufficient quantity to keep a party warm.

The
Coast
ranges.

VI. To the west of the Sierra Nevada and the Cascade range is another chain of mountains, which, although greatly inferior to these in some important respects, is still of very considerable interest—the Coast ranges of California and Oregon. They differ in being newer geologically, of less elevation, less extensively and regularly broken through by granitic axial masses, and less covered by volcanic overflows. The upheaval of the Sierra took place at the close of the Jurassic epoch, whereas that of the Coast ranges was the result of agencies operating during the later portion of the Tertiary, and continuing down to a very recent date—namely, into the post-Pliocene. The greater part of these ranges south of the Bay of San Francisco is of Miocene age, although even there extensive areas of Cretaceous rocks exist, and especially on the eastern side of this mountain belt, in the so-called Monte Diablo range. Farther north, beyond the bay, rocks of this age become more and more predominant, the areas of Tertiary being comparatively narrow and unimportant. A remarkable feature of the geology of the Coast ranges is the extent to which these newer formations have been metamorphosed, so that by some observers these altered rocks have been described as belonging to the very oldest part of the geological series. The prevalence of serpentines and obscure serpentinitoid rocks in great masses in these altered portions is also a fact of much geological interest. These altered rocks, and especially such of them as have been more or less silicified, are the home of the ore of quicksilver, mines of which metal have been opened and extensively worked at numerous points both south and north of the Bay of San Francisco. Chromic iron is also associated with these magnesian rocks, and at a few points is present in considerable quantity. Gold has been washed at numerous points in southern California, with some success. An important member of the Miocene series south of the Bay of San Francisco is the bituminous slate, which in places is several thousand feet in thickness, and often contains a large quantity of bituminous matter, which, at some localities, especially near Santa Barbara and Los Angeles, has oozed out upon the surface and given rise to areas of semi-liquid material, called “brea” by the Mexican Spanish, which has occasionally hardened and formed large deposits of asphalt. Many attempts have been made to bore into these bituminous rocks for petroleum, but these efforts have never been successful enough to furnish even the home market with a supply of oil suitable for illuminating purposes. Coal is found at numerous points in the Coast ranges, both in California and in Oregon, and of both Cretaceous and Miocene age. The most important mines are those in Washington Territory, near Seattle; and there is also a valuable and quite extensive coal-field on Vancouver Island, near Nanaimo, also in the Cretaceous. The most important and best-developed portion of the Coast ranges is that opposite or to the west of the valleys of the San Joaquin and Sacramento rivers. Both south and north of the extremities of these valleys the masses of the Coast and Sierra mountains coalesce, or become topographically so united that any distinction other than geological is impossible. This uniting of the two ranges which takes place in northern California is continued through southern Oregon, where the topography is quite as complicated and difficult as in those parts of California where the two ranges come together. But in the last-named State the structure of the Coast ranges has been pretty well worked out by the California State Geological Survey, although the maps unfortunately remain unpublished, while in Oregon almost nothing has been done in this direction. Where best developed—in California—the Coast ranges have a length of fully 400 miles, and a breadth varying from 40 to 70 according to the varying position of the coast-line. The mass of mountains covering this area is made up of numerous subranges, some of which are very distinct and well-marked, while others are much less so. These all along the north-west and south-east trending portion of the coast, or from Point Conception (34° 15' N. lat.) to Cape Mendocino, run nearly in the same direction as that coast. Their altitude above the intervening valley, in the vicinity of the Bay of San Francisco, varies from a few hundred to 3000 or 4000 feet. Prominent points near that bay are Monte Diablo (3856 feet), Mount Hamilton (4440), Mount Helena (4343), and Mount Bache (3790). As we go north and south from the region of the Bay of San Francisco, we find the heights of the dominating peaks increasing. Mount Bailey, about 150 miles north of San

Francisco, has an elevation of 6357 feet. About the same distance south of that city is San Carlos Peak (nearly 5000 feet). Portions of the range south of the Bay of San Francisco are of extremely recent date, as great masses of rock of Pliocene age, hundreds of feet in thickness, are seen to be turned up at a high angle. The ranges along that portion of the coast which has an east and west trend, on Santa Barbara Channel, have themselves the same trend, and are high and precipitous. Of these the Santa Inez is the most conspicuous, having along its crest points nearly or quite 4000 feet high. The Santa Monica, another east and west trending range, farther east and south, is remarkable as being made up of Miocene stratified rock, and having a central well-defined linear axial mass of intrusive granite, driven through it like a wedge, by which the range has been raised to a high angle near the eruptive rock, where it is extensively shattered and metamorphosed, and from which, in each direction transverse to the chain, it gradually and rapidly recovers its normal character and nearly horizontal position. Farther south along the coast the ranges are much broken, and central dominating points rise to very considerable elevations. The San Bernardino and San Jacinto Mountains are two of these elevated central masses, each rising to about 11,000 feet. The precise relations of these high masses to the Coast ranges and Sierra cannot as yet be stated. The region of the Coast ranges in California is one of very unequal attractiveness. Portions are rough and forbidding, being covered by a dense thorny undergrowth, locally known as “chaparral”; other portions are in the highest degree fertile and picturesque, and have a remarkably mild and uniform climate. The slopes and hills near the coast, or open to the west winds, have a fairly sufficient rainfall. The interior ranges, especially the portions of them west of the San Joaquin valley, are very dry, and over large areas so much so as to be unfit for cultivation.

Geology of the Mississippi Valley.

The area enclosed between the Appalachians and the Cordilleras, Mississippi extending to upwards of 1,500,000 square miles, the drainage basin of the Great Lakes and St Lawrence on the north and of the grand valley. Missouri-Mississippi river-system on the south, cannot here be discussed in detail from the topographical point of view. The general features do not present the diversity seen in the regions already considered. All that can be done here is to indicate the salient points of the geology.

The belt of Tertiary and Cretaceous rocks already mentioned as forming the Atlantic slope extends, with very similar characters, curving broadly around the southern end of the Appalachians, and continuing along the Gulf and up the Mississippi valley, to about the junction of that river with the Ohio. About half of Alabama and Arkansas, all Mississippi and Louisiana, parts of Tennessee and Kentucky, and a very small corner of Missouri are underlain by these newer formations. Nearly the whole of Texas is similarly situated with respect to its geology. In the northern central portion of the last-mentioned State the marly and gypsiferous red sandstones of Triassic age cover a large area, bordered on the south-east by a little-known coal-field, of Carboniferous age, with a very small patch of Azoic or Archæan rocks at its southern termination, almost exactly in the centre of the State. Tracing the geological formations northward from Texas into New Mexico and along the eastern flank of the Rocky Mountains, we find the belt of Cretaceous and Tertiary covering a very large area, extending as far east from the mountains as the centre of Kansas, and covering nearly all Nebraska and Dakota, the north-western corner of Iowa, and the western half of Minnesota. The Triassic belt mentioned as occurring in Texas occupies a broad area in the Indian Territory and the southern central part of Kansas. It is also quite extensively exposed along the streams of New Mexico, forming the border of the Llano Estacado or Staked Plain. The Cretaceous and Tertiary rocks of the west have nowhere anything like the economical importance which they have in New Jersey; but from a palæontological point of view they are of interest, and, especially in the lower Mississippi valley, have been studied with care and in considerable detail by the State geologists. Included within this border of more recent rocks, and comprising the whole of the North-Eastern Central group of States (see below), as well as the western portion of the North-Western Central, and smaller portions of the South-Eastern and South-Western Central groups, is a region underlain almost exclusively by Palæozoic rocks, covered with post-Tertiary and recent detrital formations, the intermediate members of the geological series being entirely wanting. These Palæozoic strata include very extensive and complete representations of both the Lower and Upper Silurian series, and also of the Carboniferous, including both the upper and lower members of this division of the Palæozoic. As we leave the Alleghany escarpment in going westward we find the disturbances of the strata becoming less and less marked, what flexures there are being exceedingly broad, so that over large areas the rocks seem to lie in an almost undisturbed horizontal position. The geographical distribution of the areas underlain by the Coal-measures in this region is indicated below

(p. 812). Calcareous and calcareo-magnesian formations are especially prominent over this great area of nearly undisturbed strata. As we proceed westwards from the Appalachian belt we find the purely detrital and siliceous rocks diminishing and the calcareous gaining in importance and thickness. Thus the millstone grit, which on its eastern edge is in places more than 1000 feet thick, is found in parts of the Mississippi valley to have diminished to a few feet, or even in places to have disappeared altogether. With this diminution of coarser detrital and siliceous material comes in a wealth of organic forms, and the rocks of the region in question have been most fruitful of material for the palæontologist. Towards the western and north-western portions of the Palæozoic area there occur several marked breaks in the uniformity of the geological character of the region. These are due to the appearance at the surface of rocks older than the lowest Silurian—rocks, indeed, which, up to the present time, in spite of forty years of diligent search, have not been found to exhibit any traces of life. For this reason these rocks, which unconformably underlie the Lower Silurian, and are in such a position as to prove beyond a doubt that they assumed that position before the deposition of the lowest known fossiliferous rocks, were called Azoic by Foster and Whitney, but are now more generally known as Archean, a name substituted by Dana. The Azoic areas of central Texas, northern Texas, and central Arkansas are comparatively small, and have been but little studied in detail, since, thus far, they have not been shown to be of much economical value. The Azoic area in south-eastern Missouri is also of small dimensions, but economically important, since iron ores, large in quantity and of great purity, occur here, at the well-known Iron Mountain, Pilot Knob, and other localities. Far more important than those already mentioned, however, is the Azoic area of northern Wisconsin and north-western Minnesota, which is in direct connexion with the great Azoic district of so much importance in Canada as forming the mass of the Laurentian mountains. The region in Wisconsin forming the divide between the waters flowing into Lake Superior and those uniting with the Mississippi is one of Azoic rocks, and from this a long spur extends westerly through Minnesota and north-easterly to Lake Superior. It is in this region and in this formation that the iron mines occur which are of so much importance to the country (see p. 814), the principal mines lying about 1500 feet above the sea or 900 feet above Lake Superior. To the north-west of this Azoic area, on the borders of the lake, is the very important copper region (p. 816). The copper-bearing range, which rises in places to an elevation of as much as 2000 feet above the sea-level, is made up of old volcanic masses interstratified with sandstones and conglomerates of Lower Silurian age. The so-called trappean range runs from the extremity of Keweenaw Point south-westerly along and near the shore of the lake, and finally disappears some distance beyond its western end; but the portion of the range which is of importance for its copper mines is in Michigan and on or near Keweenaw Point. The detrital formations which cover most of the surface of the Palæozoic area, the boundaries of which have here been indicated, are of varied character. Over much of the country the principal detrital material present is that which has been left behind by the slow wasting away, under the influence of the rain and other atmospheric agencies, of the calcareous rocks which there occur. This kind of material forms the bulk of the soil in the higher portions of the region lying near the Ohio and its junction with the Mississippi, and north-west to Minnesota. The river-bottoms grow wider as we proceed in the direction of the drainage towards the Gulf of Mexico, but the thickness of alluvial soil overlying the Tertiary and Cretaceous does not seem, in general, to be very great. The material liberated by the decomposition of the rock has been so fine that most of it has been easily carried away where the volume of water in the rivers was considerable. Coarser detritus occurs near the mountain ranges, especially those on the east, where strata made up in large part of pebbles or even boulders of quartzose or other indecomposable rocks form a considerable portion of the underlying formations. An important feature in the surface geology of the northern portion of the central area as well as of the extreme north-eastern portion of the United States, or that comprised within New England, New York, the northern part of Pennsylvania, and the region adjacent to and south of the Great Lakes, is the presence of a large amount of coarse detrital material in the form of boulders, gravel, and sand, which has been, in large part, brought from the north, and which is mixed very unequally in different regions with the material resulting from the disaggregation, decomposition, and abrasion of the closely adjacent or underlying rocks. The origin and mode of distribution of this so-called "northern drift" has long been a fruitful subject of discussion among American geologists. By far the larger number of those who, in later years, have discussed the problem have been inclined to ascribe the origin of the drift almost entirely to glacial causes. It is assumed that the northern portion of the continent was, during the so-called "glacial epoch," covered deeply with ice, and that all, or nearly all, that we see at the present time upon the surface of the region thus covered is the result either of this ice envelope or of the floods

produced by its melting. The present writer believes the phenomena to be much more complicated and difficult of explanation than is generally supposed, but contents himself with simply stating what is the current belief among American geologists.

POLITICAL AND NATURAL SUBDIVISIONS.

As politically organized at present the area included within the limits of the United States is divided into forty-nine subdivisions, including Alaska. There are thirty-eight States, eight Territories, and three subdivisions, neither States nor Territories, each of which stands in a peculiar relation to the general Government—namely, the District of Columbia, the Indian Territory, and Alaska.

In the following table of the States and Territories the names are followed by their customary abbreviations. The dates are those of admission into the Union as States; in the case of the thirteen original States (printed in small capitals), they are the dates when those States ratified the constitution. The names of the Territories are printed in italics.

TABLE I.—Area and Population of the States and Territories.¹

States and Territories.	Date of Admission.	Area in Square Miles.	Population, June 1, 1870.	Population, June 1, 1880.	Increase per Cent.	Population per Square Mile (1880).

¹ The total area (excluding Alaska) is 3,025,600 square miles,—made up by the addition of unorganized territory (6740), Delaware Bay (620), and Raritan Bay, &c. (100). The last column shows the population per square mile of the land surface, which amounts in all to 2,970,000 square miles.

As long as the population of the country was limited to the Atlantic and Gulf coasts there was no difficulty in classifying the divisions geographically; the Northern, Middle, Southern Atlantic, and Gulf States constituted a natural grouping. The almost unknown and at that time not easily accessible region beyond them to the west was known as "the West," and by this term until more than a quarter of the present century had elapsed the valley of the Mississippi and its tributaries on the east was designated. It was not until about the middle of the century that a still farther "West" began to be taken into consideration.

Early in the history of the country the six north-eastern States (Maine, New Hampshire, Vermont, Massachusetts, Rhode Island, and Connecticut) received the still current designation of New England. And till after the Civil War there was the division of the States into Southern or Northern, according as slavery was or was not permitted.

The suggestion was made by Mr Gannett, geographer of the census of 1880, "to divide the country into three great divisions,—

the Atlantic region, the region of the Great Valley, and the Western or Cordilleran region." The region of the Great Valley he calls the Central region, and this is again subdivided into two parts—the Northern Central and the Southern Central—by the Ohio river and the southern boundary of Missouri and Kansas. The Atlantic division is also subdivided, by a line following the south boundary of Pennsylvania and New Jersey, into the North Atlantic and South Atlantic divisions. The Western or Cordilleran division is limited on the east by the eastern boundaries of Montana, Wyoming, Colorado, and New Mexico. A farther subdivision will be found convenient at times, the Northern Central region being divided into two parts (the North-Eastern and the North-Western) by the

Mississippi, and the Southern Central also into two parts (the South-Eastern and South-Western) by the same river. The Western or Cordilleran division may be naturally divided into the Rocky Mountain, the Plateau, and the Pacific Coast regions. Adopting the scheme thus suggested, we have the following grouping of all the States and Territories of the United States (Table II.), the only differences between this scheme and that of Mr Gannett, besides those already indicated, being that the Atlantic States are divided into three subdivisions—the Northern, Middle, and Southern,—and that West Virginia is placed with the Central States because its drainage is to the Ohio and in its physical characters it is allied to the North-Eastern Central group.¹

CLIMATE.

Plate IX. From the Atlantic seaboard west to near the base of the Rocky Mountains the lines of equal mean temperature have a considerable degree of regularity, running approximately east and west. When, on the other hand, we reach the borders of the Cordilleran region we find the isothermal lines suddenly deflected from their normal course, and in passing across the mountain and plateau belt we find them irregular, often concentric over large areas and through great ranges of temperature, according as the altitude, width, and general trend of each separate range or system of ranges make their influence felt. Hence there are three distinct climatic divisions of the United States:—(1) the eastern region, from the Atlantic to the foot of the high plateaus at the base of the Rocky Mountains; (2) the plateau and mountain region of the Cordilleras; (3) a narrow strip on the Pacific coast, lying west of the Sierra Nevada and the Cascade range. These three divisions are of very unequal size and importance. The first embraces about three-fifths of the entire country, and contains fully nineteen-twentieths of its population; the second is also much larger than the third, containing not much less than a million square miles, but is very sparsely peopled. The third is more densely peopled than the second, but small in area, although its limits are not capable of being accurately defined. These three divisions will here be designated the Eastern, Cordilleran, and Pacific.

In the Eastern division the passage from one type of climate to another is gradual and uniform, though rapid. The difference in climate between the eastern and western coast of the Atlantic was long ago noticed and commented on. It was George Forster who first controverted the prevailing idea that the New World in general was colder than the Old, and recognized the analogy between the climates of the eastern coasts of the Atlantic and Pacific. Humboldt afterwards investigated the facts and published a tabular statement, which, as enlarged by Hann, is here presented (Table III.):—

Place.	Latitude.	Mean Temperature of the			Difference. Year.
		Year.	Coldest Month.	Warmest Month.	
Nain, Labrador.....	57 12	25.18	3.82	51.08	21.6
Aberdeen, Scotland.....	57 12	46.76	37.22	57.74	
St John's, Newfoundland...	47 36	40.10	22.46	59.54	
Brest, France.....	48 24	53.60	43.44	64.76	11.7

Norfolk, Virginia.....	36 50	59.18	40.28	78.62	
San Fernando, Spain.....	36 30	63.50	52.70	76.10	4.3

From the above table it will be seen that the difference between the mean annual temperature of places in high latitudes on the opposite sides of the Atlantic is very large, and that it diminishes

as we go south. About lat. 30° the two sides of the Atlantic have nearly the same mean temperature, the difference in climate being very great, but chiefly dependent on differences in the amount of precipitation. Nearly the whole area of the United States is included between the annual isothermals of 44° and 68°—a difference of 24°, the corresponding difference of latitude being about 15°. The average change of temperature is, therefore, 1.6° for each degree of latitude,—the most rapid change of temperature with the latitude known in any region of anything like equal extent. The causes of the rapid increase of temperature in going south along the Atlantic seaboard are the position of the Gulf of Mexico, the high temperature of its waters, and the increasing predominance of south-westerly winds. From these circumstances the southern portion of the Atlantic coast of the United States is decidedly warmer than the regions corresponding to it in latitude on the west side of the Pacific, while farther north places in the same latitude on the west sides of the two oceans have approximately the same temperature. This similarity of temperature on the corresponding sides of the Atlantic and Pacific is the result of causes now easily understood, the chief being the position of the mass of the land with reference to the direction of the prevailing winds. From the Atlantic coast to the eastern base of the Cordilleras the isothermal curves for the year are nearly parallel, and have a general east and west course, being only interrupted in this regularity and deflected to a certain moderate extent in passing across the Appalachian chain, which nowhere rises high enough to give a chance for permanent accumulation of snow. These curves, of course, are roughly parallel to the coast-line of the Gulf of Mexico, which over a breadth of fourteen degrees of longitude does not vary much from an east and west direction. The region over which a higher mean annual temperature than 68° F. prevails includes nearly the whole of Florida and a narrow strip along the Gulf, which widens rapidly in Texas, where the trend of the coast-line suddenly becomes nearly north and south. The extreme south end of Florida, which just touches 35°, has a mean temperature of over 72°, the isothermal of 76° being nearly on that parallel. The isothermal of 64°, which meets the Atlantic coast near the borders of North and South Carolina, keeps nearly on the parallel of 34° as far west as about 100° W. long., where it is rapidly deflected southward, in conformity with the direction of the other isothermals, by the gradually increasing elevation of the country when the plateau region is encountered. The isothermal of 60° is nearly parallel to that of 64°, except that it manifests the influence of the high southern extremity of the Appalachians, and is in consequence considerably deflected to the south between the meridians of 83° and 87°. The

¹ The name Cordilleran is preferred for the Western division, because thereby any confusion is avoided which might arise from the fact that the people of the eastern States are still more or less inclined to call any portion of the region lying to their west by that name. No grouping in which all the States and Territories are included can be entirely satisfactory; but in that here suggested they are, while geographically connected, in most respects pretty closely allied to each other by their physical, climatic, and agricultural characters.

isothermal of 52° is, to the west of the Appalachians, nearly coincident in position with the Ohio river as far as Cincinnati, and thence follows an undulating course, with a nearly westerly general direction, through Indiana, Illinois, northern Missouri, and along the northern boundary of Kansas to the border of Colorado, where it is suddenly deflected and runs with a nearly southerly course for a distance of fully 500 miles along the eastern base of the Rocky Mountains. Those portions of the country which lie between the isothermals of 44° and 52° are New England, with the exception of Maine and the northern part of New Hampshire and Vermont; New York, excluding the extreme north-eastern corner (the Adirondack region); the Appalachian plateau region on the borders of New York and Pennsylvania; nearly all Ohio; two-thirds of Indiana and Illinois; nearly all Michigan and Iowa; southern Wisconsin; south-eastern Minnesota; nearly all Nebraska; and the southern half of Dakota. The isothermal of 40° passes through the centre of Maine, cuts off the extreme northern end of New Hampshire and Vermont, then passes out of the United States, re-entering at the west end of Lake Superior, passing through the centre of Minnesota, making a large loop to the south in eastern Dakota and then trending north-westwardly until it passes beyond the boundary line of the United States in 107° W. long.

Within the Cordilleran region, or west of the 105th meridian, the position of the isothermals is largely dependent on that of the mountain ranges, which rise high enough profoundly to influence the climate, though it is only at a few points, especially round the summits of the lofty volcanic cones near the Pacific coast, that they reach the region of perpetual snow. This deficiency of lasting accumulations of snow, however, is in very considerable part due to the smallness of the precipitation. Observations of temperature on the higher ranges are extremely deficient. On Mr Schott's temperature chart (Plate IX.) the isothermal of 44°, which, as already mentioned, east of the Cordilleran region nearly coincides with the northern boundary of the country, encloses within a great southerly-reaching loop the whole of the higher portion of the Rocky Mountains, extending as far south as the 34th parallel, or to about the position in latitude of the isothermal of 60° in the eastern division of the country. The crest of the Sierra Nevada, Cascade, and Blue Mountain ranges is also within the curve of 44°. The highest portion of the Rocky Mountains, as far south as 39° N. lat., is laid down as having a mean temperature lower than 36° F. The whole of the Great Basin and the Columbian plateau is indicated as having a considerably higher temperature than the dominating system of ranges which enclose it on the east and west. Considerable bodies of snow remain on the summits of the ranges during a large part of the year, at least as far south as 39° N. lat. In the plateau region of Arizona, Utah, and Nevada the decline of the ranges, the generally lessening elevation of the region, and the facility of access which the topographical conditions allow to the heated air from the south give a high temperature, and the isothermals form irregularly concentric loops extending from the head of the Gulf of California northwards. The isothermal of 52° reaches as far north as Virginia City, in lat. 39°, and that of 72° extends to Fort Mohave, in lat. 35°.

In strong contrast with the Eastern division, we find in the region bordering on the Pacific a very marked tendency to a parallelism of the isothermals with the trend of the coast; consequently, a very moderate change in the mean annual temperature may be met with over a large range of latitude. The character of the isothermals here is greatly modified by the position of the two parallel ranges, the Coast Mountains and the Sierra Nevada, which enclose valleys of great extent but of low altitude. In general the temperature of the Pacific coast-belt is much more uniform and higher than that of the Atlantic side of the United States. The isothermal of 60° runs nearly parallel with the coast, and not far distant from it, from the southern line of California north through nearly three degrees of latitude. The isothermal of 52° approaches San Francisco in lat. 37° 48', and keeps near the coast to as far north as lat. 47°. A higher mean temperature than 48° prevails over the region adjacent to Puget Sound, at the northern boundary of the country, in lat. 49°, while the mean temperature of the northern part of Maine, between the parallels of 45° and 47°, is below 40°. Thus it may be said with truth that near the Pacific coast we have a difference of only 12° in mean temperature in a range of over sixteen degrees of latitude. And if we pass from the immediate vicinity of the coast in lat. 35° into the San Joaquin and Sacramento valleys, we may range over five degrees of latitude and keep in a region of which the mean temperature is not below 60° and nowhere much higher. The causes of this are the proximity of the great area of water from which the prevailing winds blow, the modification which the temperature of this ocean undergoes near the American coast by the Asiatic coast current and the northern or Arctic coast current, and the position of the mountain ranges near the coast. Uniformity of climate along the edges of the land is still further aided by the peculiar nature of the currents along this coast. The influence of the warm Asiatic current—the Kuro-Siwo—is distinctly felt in raising the temperature as far south as the northern

border of California, while farther south the cold Arctic current, which apparently emerges from under the warm current, makes its cooling presence felt along the coast nearly or quite as far as the southern boundary of the country.

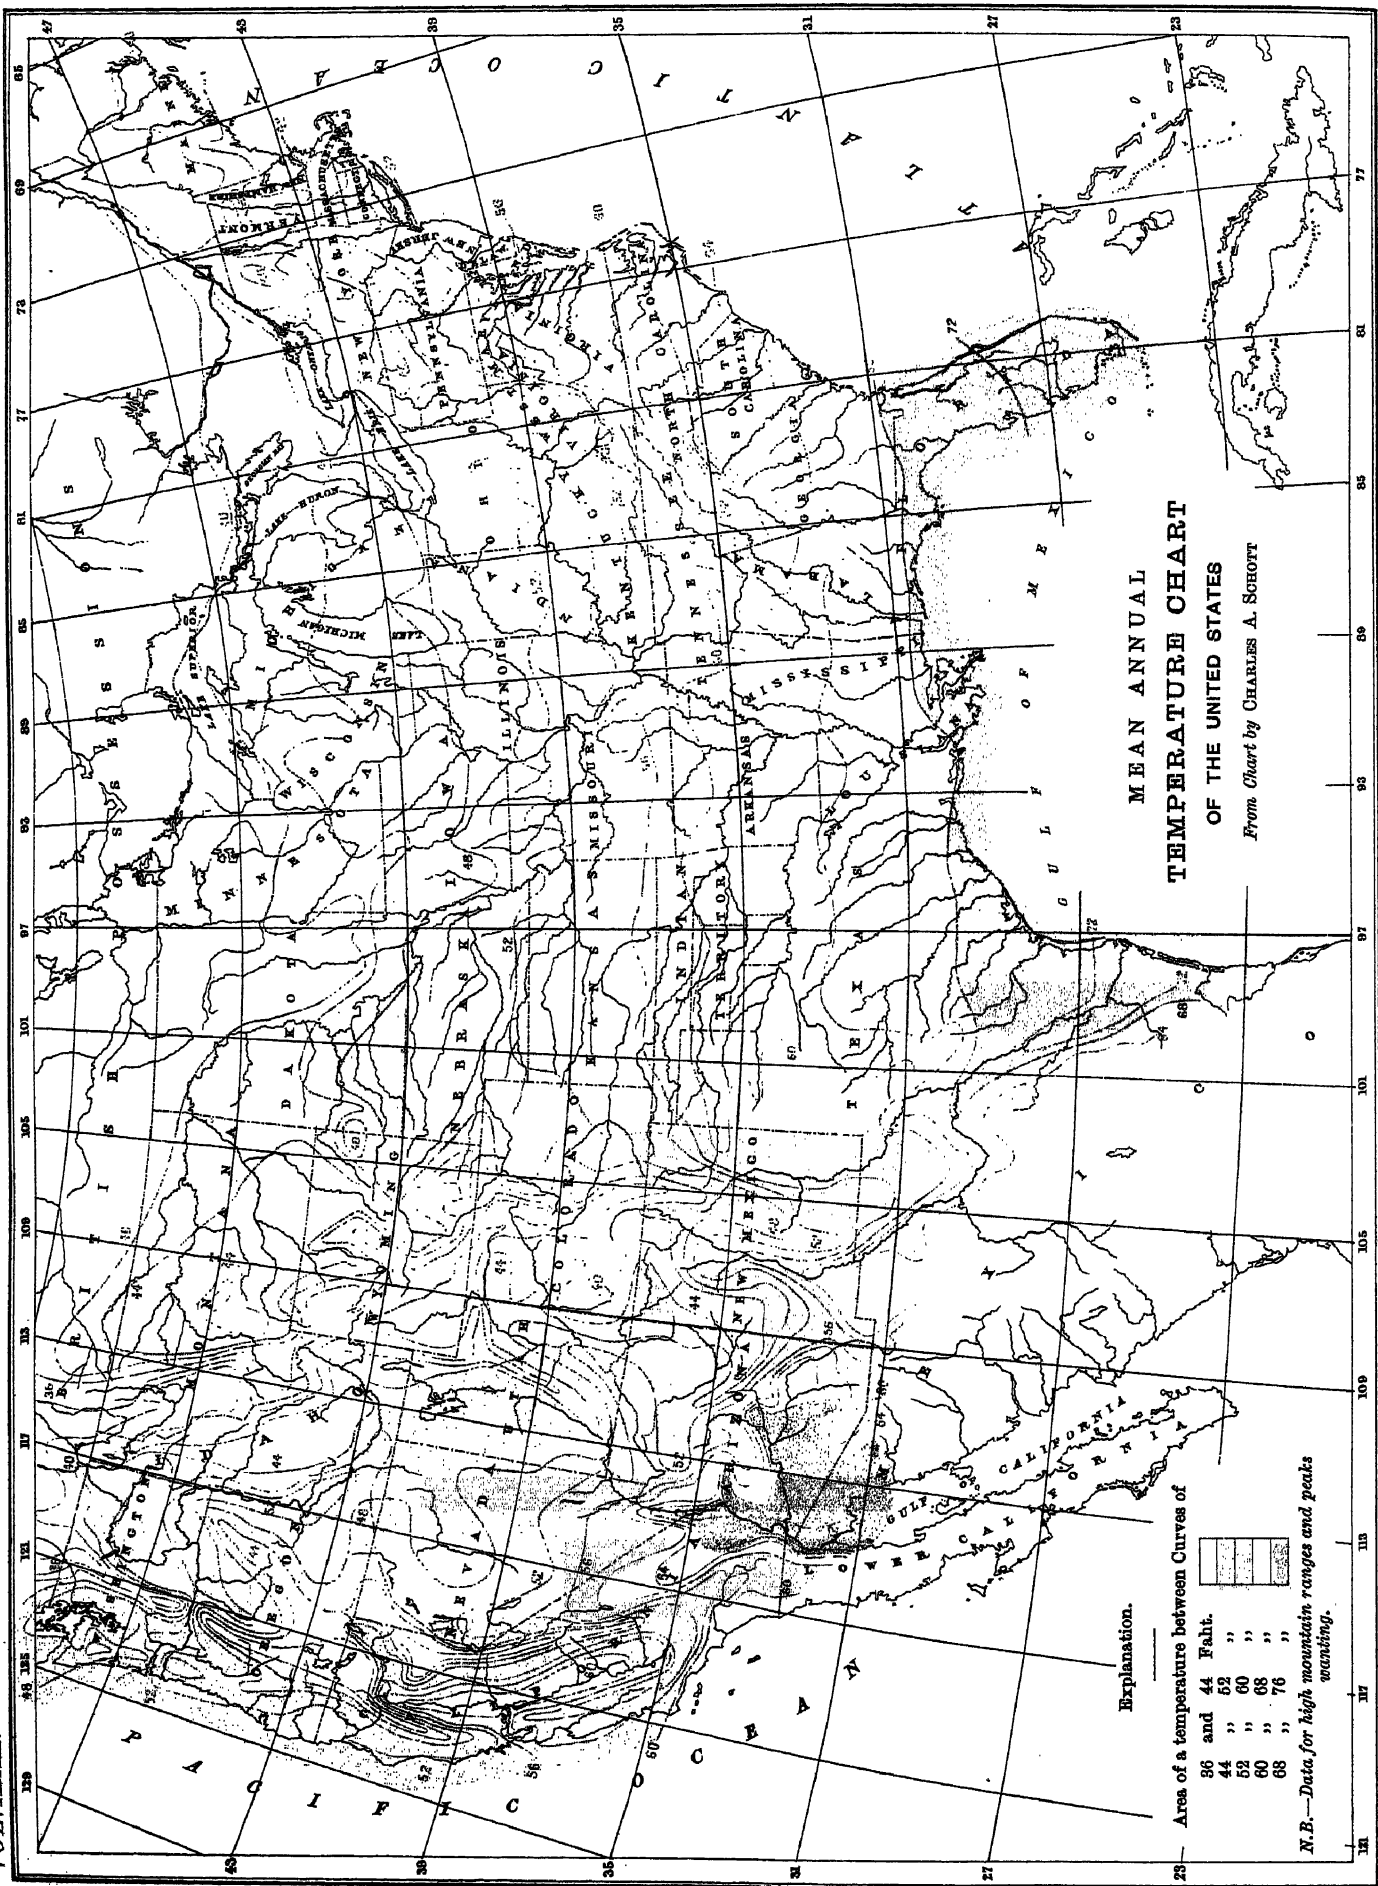

The isothermals for the summer months (June, July, and August) Summer are much more irregular than those of the year, especially in the iso-Eastern division. The powerful heating influence of the Gulf of thermals, Mexico, swept over in summer by southerly winds, makes itself extremely apparent in the summer isothermals, which bend to the north-west in a most remarkable manner, that of 72° reaching as far as the centre of Dakota, or beyond lat. 45°. A mean summer temperature of 80° and upwards prevails over Florida, a considerable portion of the Gulf States, and nearly all Texas. The belt adjacent to the Ohio, extending north as far as the Great Lakes, south along the Appalachian tableland into Tennessee and the north-western corner of Georgia, and west through Iowa, Nebraska, and northern Kansas, lies between the summer isothermals of 68° and 76°. The summer isothermals along the Pacific coast are much less considerably changed in position and character from their mean annual character than they are on the Atlantic side, for reasons which have been already given, while the irregularity and complexity of the summer curves in the Cordilleran region generally would be very distinctly noticed if the data were at hand and could be exhibited with some detail. An extraordinarily high temperature prevails in summer in the southern portion of the Great Basin and in the Arizona plateau region, the isothermal of 88° surrounding with its northerly-reaching loop a large area in the lower valley of the Colorado river and extending north as far as lat. 35°. The winter (December, January, February) isothermals Winter in the Eastern division have more of the regularity of the annual iso-curves than have those of the summer. The winter isothermal of thermals, 52° coincides very nearly with the mean annual curve of 68°, keeping near and closely parallel to the Gulf of Mexico. The winter isothermal of 32° runs from Cape Cod across Long Island to New York city, and across New Jersey, thence making a large loop to the south so as to surround the Appalachians, and, after ascending northerly again on the west side of that range to near the Ohio, passing through Indiana, Illinois, Missouri, and Kansas, thence descending in a south-westerly direction and sweeping around the Rocky Mountains, and through the centre of the Great Basin in a very irregular course. On the Pacific coast the form of the winter curves closely resembles that of the yearly isothermals. The winter curve of 52° very closely coincides with that of 60° for the year, and the winter curve of 40° runs from near San Francisco, closely parallel to the coast and at a little distance from it, as far as Cape Flattery, or through a distance of over ten degrees of latitude.

The irregular, non-periodic fluctuations of the temperature are Irregular of great interest, and without knowing what these are one would fluctua-form a very false idea of the real character of the climate. It does tions of not appear that these fluctuations greatly affect the general salubrity tempera-of the country, but they have a marked effect on the character of turethe vegetation, as well as on the methods of cultivation. The occasional occurrence of very low temperatures in low southerly latitudes where the mean winter temperature is quite high is one of the most striking phenomena in the climate. Savannah, as Hann remarks, has a mean winter temperature the same as that of London and Cadiz, although this latter city lies 4½° farther north. But the vegetation of the two regions is essentially different, because frosts do not occur in that part of the Spanish peninsula. Orange trees are liable to become entirely frozen everywhere in the United States except in southern Florida; this is not the case in Spain. The cotton plant is a perennial in the south of Spain, while, on the other hand, the stem and branches are killed every year by frost in the United States, so that the fields have to be annually replanted.

The following table (IV.), from data arranged by Hann, gives an idea of the range of temperature in various parts of the country:—

	Latitude.	Mean Monthly Range.		Mean Yearly Extremes.	
		Winter.	Summer.		
Fort Sully.....	44 39	103·5	90·1	—25·2	108·7
Fort Snelling.....	44 58	93·2	70·3	—25·2	93·0
St Louis.....	38 37	90·3	73·2	— 5·8	99·7
New York.....	40 42	79·0	71·2	0·7	93·0
Macon.....	33 46	80·2	59·7	18·3	97·2
Charleston.....	32 45	73·4	52·3	24·1	92·7
New Orleans.....	30 0	78·6	55·6	23·2	96·2

The region of lowest winter temperature is that along the eastern border of the Rocky Mountains in the northern portion of the country, where the temperature not unfrequently sinks so low as to freeze mercury. The lowest temperatures observed in this region, as given by Schott, are—at Fort Sanders, in Wyoming, —50°; Fort Ellis, Montana, —53°. A temperature low enough to freeze mercury is occasionally observed in Wisconsin and Michigan, and on the borders of Canada and New York. The hottest region

is that along the lower portion of the Colorado and Gila rivers in Arizona and the adjacent part of California.

Cold waves. An excellent illustrative example of the suddenness and severity of the "cold waves" which occasionally pass over the country is afforded by the facts gathered by the Signal Service in regard to an occurrence of this kind in January 1886.

The barometer was high from the Rocky Mountain region to the Pacific coast on the 2d, and from that date to the 5th a slow north-easterly movement of this high area was observed; after the 5th there was an apparent increase of this high area from the region of the Saskatchewan valley and Manitoba. On the afternoon of the 6th the observers in Wyoming, Colorado, Nebraska, Kansas, and Missouri were warned of the approach of a "cold wave," accompanied by a "norther," and of a probable fall of temperature of 20° to 25° in the next twenty-four hours. The centre of greatest barometric pressure remained north of Dakota from the 6th to the 12th, but the cold wave had reached the Gulf coast and Florida before that date, causing in many places a lower temperature than has been observed in many years, and in some a lower one than had ever before been known. In Kansas many persons were frozen to death, and the loss of stock was very great; at Dodge City the wind blew with a velocity of 40 miles an hour, the thermometer averaging during the day 10° below zero. In Mahaska county, Iowa, from the 7th to the 11th twenty persons perished with the cold, and much stock was lost. Similar reports came from other parts of Iowa. In Memphis, Tennessee, the thermometer fell to 8° below zero. In Nashville, from the 9th to the 10th, the cold was the severest on record. In New Orleans the cold wave struck the city at 3 A.M. on the 8th, and the thermometer stood at 15°-2 on the morning of the 9th. At Indianola, Texas, the coldest weather experienced for several years occurred from the 8th to the 13th; on the 12th snow fell to the depth of 3 inches. At Galveston the cold was the greatest ever known, the mercury falling to 11°, being a fall of 54° in less than eighteen hours. A heavy snowstorm set in on the morning of the 12th, covering the ground to the depth of 6 inches, and causing much loss and suffering. At Mobile, Alabama, the minimum on the morning of the 9th was 11°, and at Montgomery, 5°-4. In Florida the cold was very severe; ponds were frozen over, and much fruit frozen on the trees. At Atlanta, Georgia, the mercury fell to 2°-4 below zero. At Savannah it stood at 12°, the lowest ever recorded at that place. At Charleston, S.C., it stood at 10°-5; ice 3 inches thick formed on the ponds. On the morning of the 11th, the curve uniting points of which the temperature was zero ran from Dakota south nearly to Arkansas, thence across to the Atlantic, passing south of Knoxville, and up the coast to Nova Scotia. On the St Lawrence and beyond it to the north-west, the mercury stood at from 10° to 30° below zero. This cold wave was remarkable, not only for its severity, but because it extended so far to the south and caused so much damage. The whole country east of the Rocky Mountains was brought under its influence. Of the rapidity of its progress an idea can be formed from the statement that the first warning was issued from the Signal Office at 12h. 2m., January 7th, for the extreme north-west, and that for New England just two days later. This area of high barometer moved eastward, after the 12th, to the Atlantic coast, following the coast-line, passing over Nova Scotia, and disappearing to the eastward on the 16th.

It appears from Prof. Loomis's working over of the records of the Signal Service that throughout the greater part of the United States there is occasionally observed a difference of as much as 40° between the maximum and minimum of the same day, and that there are a few places where such changes are remarkably frequent. These places seem to be all west of the 95th meridian, and at or near the base of the Rocky Mountains. Thus, in 1874 there were thirty-eight stations at which a difference of 40° on the same day between the maximum and minimum temperature was observed. At Colorado Springs (5935 feet) this happened fifty-six times, at Denver (5135 feet) forty-five times, and at Cheyenne thirty-three times; at seventeen stations it happened only once. At Denver, 15th January 1875, the thermometer fell 48° in one hour; and an observer "who is pronounced perfectly reliable" reported a fall in temperature at that place of 36° in five minutes. These changes of temperature felt at Denver were the concomitants of a considerable storm, which came from the north-west, and whose centre passed about 250 miles east of that place.

Hot waves. The occasional occurrence of "hot waves" which sweep over large areas of country, raising the temperature much above its normal height, is one of the most striking and most disagreeable features of the climate of the country, and especially of its northern and north-eastern portions. There is rarely a year in which one or more of these abnormal occurrences are not observed; and, although they do not usually last more than two or three days, they are sometimes prolonged for a month or more, in a succession of heated periods with little or no interval between them. Thus, for example, in July 1885 the thermometer at West Las Animas, Colorado, rose on the 15th to 105°-2; at Albany, N.Y., on the 17th, to 96°-6; at New London, Conn., on the 18th, to 92°-4; in New York city, on the 21st, to 95°-9; in Baltimore, Md., on the 20th and 21st, to 98°-3 and 98°-7; at Dubuque, Iowa, on the 20th, outdoor work was suspended on account of the intense heat. Again, a little later, in Dayton, Washington Territory, on the 28th of the same month, the temperature rose to 102°-6; at Milwaukee, Wis., on the 28th, to 92°-8; at Fort Sully, Dakota, on the 29th, to 104°-5; at Yankton, Dakota, on the 30th, to 100°-7; at Dubuque, Iowa, on the 30th, to 97°-1; at Des Moines, Iowa, on the 30th, to 100°-1. All through the country many cases of sun-stroke occurred, eighteen fatal cases having been recorded in Baltimore during the week ending with the 25th.

Winds. The prevailing winds, as in other regions lying in the latitude of the return trades, are westerly. The extreme southern part of the country is just on the border line where the influence of the causes by which the trade-winds are originated cease to be felt. In the autumn, however, in the southern Atlantic States there is some approach to the conditions of the trade-wind region. At that season the winds in Florida and along the northern edge of the

Gulf are decidedly north-easterly as far as 33° N. lat. Farther south the Florida Keys and the northern Bahamas belong, to a certain extent, to the trade-wind region.

Along the whole extent of the Atlantic coast region westerly winds predominate during the entire year, but they are chiefly south-westerly in summer and north-westerly in winter. In the following table (V.) the direction of the summer and winter winds is given in percentages of the total amount, for the districts named:—

	Summer.						Winter.					
	N.	N.E.	E.	S.E.	S.	S.W.	N.	N.E.	E.	S.E.	S.	S.W.

In the region between the Mississippi and the Appalachians, southward as far as the Cumberland range and north to Lakes Michigan and Huron, south-westerly and westerly winds prevail during both summer and winter. There is an extensive region in the south-west of the United States, embracing an area equal to about one-third of the whole country, in which the winds of summer are chiefly southerly, varying between south-east and south-west, while in the winter they are mostly north and north-west. This region extends from the extreme south-east of California, through Arizona, New Mexico, southern Utah, Texas, Arkansas, eastern Colorado, eastern Wyoming, Kansas, and Nebraska, to Missouri. Farther north, in Wisconsin, Minnesota, and northern Michigan, south winds prevail in the summer, but in winter there is no such marked predominance of northerly and north-westerly winds as in the region to the south-west. The influence of Lake Superior is clearly indicated in northern Wisconsin, where the prevailing winds in summer are from the lake and in winter from the land. On the Pacific coast the winds have a decidedly westerly character; but in the winter this preponderance is much less marked than in summer. On the coast of Washington Territory south-east is the prevailing direction, these winds being probably the south-west winds of the Pacific coast deflected by the mountains which lie close upon the ocean. In the interior of Washington Territory south-west is the prevailing direction in both summer and winter. On the California coast the winds are very strong and steady from the north-west in the summer, but more to the south-west in winter. In summer the intensely heated plateau to the east draws the air from the Pacific, which blows with violence through every depression in the coast ranges towards the heated land-mass. There is no "wind-gap" in the Coast ranges from the Columbia river to Santa Barbara so deeply and widely cut as that of the Golden Gate at San Francisco. At this point the cool winds from the sea find entrance to the Great Valley of the Sacramento and San Joaquin, and the mass of air thus set in motion spreads itself out fan-like after passing through the Gate, so that the prevailing winds in those valleys are in summer always from the Bay of San Francisco towards the mountains. The hotter the weather in the interior the more violent is the wind at San Francisco. But this condition is limited to the daytime. At night the rapid cooling of the higher plateau checks or stops altogether the indraught of air, and an almost entire calm prevails at San Francisco, while the cool air flows in a gentle breeze down the slopes of the mountains, in a reverse direction from that which it had during the daytime. In the winter the westerly direction of the winds in this region is still greatly predominant, but the prevailing westerly current of air is not intensified in its motion as it is during the summer. Over the plateau and mountain region included between the Sierra Nevada and the Rocky Mountains the surface winds are irregular, being governed by the topography of the country; but the upper currents are, in general, from the west. In the southern part of this region, in the valley of the Gila and the lower Colorado, there is a large area which is intensely heated in summer, and towards which the winds blow from the lower region to the south, and especially from the Gulf of California. Here the predominance of southerly winds in summer is very great; but the mountain ranges to the west have so declined in height in this southern region that westerly winds are nearly or quite as common as northerly ones. Farther east and north-east, as has been seen, the preponderance of northerly winds in winter is very great.

In reference to precipitation the territory of the United States Rainfall may be divided into two nearly equal portions by the meridian of 100°, the region to the east of that meridian being one of sufficient and pretty regularly distributed rainfall, while that to the west is irregularly and insufficiently supplied, with the exception of a narrow belt on the Pacific coast, over a part of which the precipitation is irregular, but fairly sufficient, while another portion is very abundantly supplied with moisture.

Regions of less than 20 inches of precipitation must be essentially

pastoral, or, where the amount falls considerably lower, uninhabitable or even deserts. For regions where the precipitation is between 20 and 25 inches cultivation of the soil may be on the whole possible, but will be liable to serious drawbacks, since the smaller the rainfall the greater the liability to a series of years when it will fall below the mean, with partial or total failure of the crops and consequent suffering. Of course, in regions favourably situated for artificial irrigation much may be accomplished in the way of making up for deficient precipitation. If in the light of these preliminary remarks we consult Mr Schott's rainfall charts of the United States we find that the whole of the Eastern division of the country is well supplied with moisture. The isohyetal of 26 inches, which may be taken as approximately the dividing line between a sufficiently and an insufficiently watered area, crosses the northern boundary to the north-west of Lake Superior, runs south-westerly to the 97th meridian, which it strikes in about the latitude of St Paul (45°), and runs thence very nearly south, with a slight westerly inclination, so that when it reaches the northern border of Texas it has advanced westward as far as the 99th meridian, near which it remains through four degrees of latitude, to the parallel of 31°, when it again advances about four degrees to the westward, and then runs south-easterly to the Gulf of Mexico, near the mouth of the Rio Grande. As thus indicated, the isohyetal line of 26 inches leaves to the east, or in the moister region, a large part of Minnesota, the eastern edge of Nebraska, rather less than half of Kansas, most of the Indian Territory, and about half of Texas. The line of 20 inches crosses the northern boundary of the country at about the 97th meridian, and runs south with moderate undulations, gaining a little in westing, so that in the centre of Texas, on the 31st parallel, it is in about longitude 102°. Thence its course is south-easterly to the Gulf, in a course nearly parallel to the isohyetal of 26 inches, and at a very short distance from it. The isohyetal curve of 32 inches, or that marking the western limit of abundant precipitation, is in general pretty nearly parallel to that of 26 inches, and not far distant from it, so that in general it may be said that we pass from a region where precipitation is abundant to one where it is decidedly insufficient in traversing a belt of country having an average width in longitude of about three degrees. The only important exception is that towards the north the distance between the isohyetal lines widens rapidly, that of 32 inches having an almost easterly course along the southern shore of Lake Superior and the northern of Huron. Moreover, there is in the lines of 26 and 32 inches a marked loop running to the south-east, so that almost the whole of Minnesota is brought within the area over which the precipitation ranges between 20 and 32 inches, considerably the larger portion having over 26 inches. The position of the curve of 32 inches is such that a small part of eastern Wisconsin, a portion of eastern Michigan, and a small irregularly shaped belt in New York south of Lake Ontario lie in a region of less than that amount of rainfall.

The regions of largest precipitation are those bordering on the Gulf of Mexico and the Atlantic. Along the Gulf the rainfall between the meridians of 85° and 92° exceeds 56 inches in amount, and the curve of 56 inches extends northward so as to embrace a portion of Arkansas, Tennessee, Georgia, and South Carolina. There is no part of the Atlantic coast, except the extreme end of Florida, where the precipitation is as large as 56 inches. At various points the average is above 50, as in eastern North Carolina, the line of 44 inches running nearly parallel to the coast, and not far from it, as far south as lat. 37°, when it bends westwardly. The greater part of the Eastern division of the United States thus enjoys a sufficient but not over-abundant amount of precipitation, namely, that coming within the limits of 32 and 44 inches. Small areas in several of the States, however, have somewhat over 44 inches of rainfall. In the region of sufficient and in places abundant rainfall thus designated there is, on the whole, no such thing as a clearly-defined rainy season. Along the Atlantic sea-coast from Portland to Washington, through the Hudson river valley, Vermont, northern and western New York, in the Ohio valley from western Pennsylvania to Missouri, south to Arkansas and down the Mississippi to its mouth, the rainfall is pretty uniformly distributed throughout the year. There are, however, local peculiarities in the distribution. Thus, in the Atlantic sea-coast region, as far south as Washington, there are three nearly equal maxima, about the middle of May, August, and December. In the region adjacent to the Hudson river valley through to western New York two maxima are indicated, one early in July and one about the middle of October, while there is one principal minimum, early in February. In the Ohio river valley, west to Missouri, there is one principal maximum and one principal minimum, the former early in June, the latter early in February. In the lower Mississippi valley and in that of the Red River there is one principal maximum and one principal minimum, the former early in December, the latter about the middle of October; there is also a secondary maximum in July, and a secondary minimum in June. In the Mississippi delta and along the Gulf coast eastward in Alabama and Mississippi there are two maxima, the principal one about the end of July, the

secondary one early in December, while there are a principal minimum early in October and a secondary one towards the end of April. Along the upper Mississippi, in central Minnesota and part of Wisconsin, there is a decided tendency to a condition of summer precipitation and winter drought; there are two maxima, a principal one about the end of June and a secondary one about the middle of September, and a principal minimum about the beginning of February. This is a similar condition of precipitation to that prevailing in the Hudson river valley and westward, except that in the upper Mississippi region the range is much larger. Again, on the Atlantic coast from Virginia south to Florida there is also a strongly-marked prevalence of summer rains, there being one maximum of very large range late in July or early in August, with two small adjacent minima about the middle of April and late in October. There are also subordinate maxima in March and December.

On the Pacific coast the increase in the amount of precipitation as we go northward is a very marked feature of the climate. Thus at San Diego the mean of the series from 1850 to 1874 is given at 9.31 inches; that of San Francisco, for nearly the same years, at 21.49; that of Astoria at 77.61. Along the coast of California, as well as in the interior of that State in the valley and on the western slope of the Sierra Nevada, there is an almost entire absence of rain during the summer months, and a strongly marked maximum in December. Farther north, with the great increase in the total annual amount of precipitation already noted, there is also an increase in the rainfall of the summer, which amounts in the extreme north-western corner of Washington Territory to 10 or 12 inches during the three summer months. A large portion of the precipitation in the higher region of the Sierra Nevada is in the form of snow, of which the amount in different years appears to be very variable. Indeed the same thing may be said of precipitation in general on the coast of California. The largest amount of rainfall at San Francisco during the years 1851 to 1874 is given by Mr Schott as 36.02 inches, the smallest 11.73. All through the Cordilleras, from the summit of the Sierra Nevada east to the Rocky Mountains, the statistics of the precipitation are meagre, and have been very irregularly taken. The amount in general is quite small. No doubt the precipitation on the higher portions of the Cordilleran mountain ranges is considerably higher than it is in the valleys, as is indicated by the records kept by the Signal Service at the station on the summit of Pike's Peak (14,134 feet), the average for 1874-80 being 31.65 inches. In the Cordilleran region generally the fact that the precipitation is larger on the mountain ranges than it is in the valleys, and that it is chiefly in the form of snow, is a matter of great importance. When the ranges are lofty and wide enough to collect and store away a large supply of snow, this by its melting furnishes water enough to irrigate the slopes and valleys, so that they can be cultivated; when, on the other hand, the ridges are low, they, as well as the valleys at their bases, are absolutely sterile.

Those abnormal disturbances of the atmosphere which are accompanied by rain and wind may be classed under two heads,—ordinary storms, and those of destructive violence, or tornadoes. The former extend over wide areas, and are ordinarily attended by no evil results; the latter are limited to comparatively narrow belts, and are often very destructive. The ordinary storms of the United States begin with the formation of areas of low barometer, which are first heard of in the far west or south-west, and move towards the east or north-east with a velocity averaging for the entire year, as shown by Loomis's investigation of the Signal Service Records for the years 1872-84, 28.4 miles per hour, the velocity being greatest in February and least in August, the former velocity 50 per cent. greater than the latter, and the velocity varying also very greatly for the same month in different years, the average velocity for the entire year being about two-thirds greater than it is in Europe. The direction in which these storm centres advance in the remote western stations—as, for instance, Bismarck, long. 100° 38'; Fort Sully, long. 100° 36'; Breckenridge, long. 96° 17'—is towards a point considerably south of east, but at the more eastern stations it is a little north of east. In general, probably about half the storms of the country advance from the extreme north-west in great curved lines beginning with a south-easterly direction, and passing out of the country in a direction a little north of east, or, in general, following a track nearly parallel in position to the Great Lakes and the St Lawrence. The remainder of the storms of the Atlantic coast region begin in the south-west and travel north-east, or begin in the south and follow the coast-line pretty closely. In general the area of rainfall attendant on the advance of the centre of low barometer is in advance of the progress of that centre nearly in the direction of its average progress. The diameter of the rain area is variable, often much over 1000 miles. In the case of the great rain storms happening between the years 1873 and 1877, as investigated by Loomis, there were found to be, in many cases, quite a large number of independent rain centres prevailing simultaneously within the general rain area. In one case there were as many as eight of these, and there were only nine cases in which there was

not more than one area in which the rainfall exceeded half an inch. The average distance of the principal rain centres from the centre of low pressure was about 400 miles.

Tor-
nadoes. The occurrence of tornadoes in the United States is a matter of importance on account of their frequency and their destructiveness, and much has been published in regard to them. A large amount of information will be found in a publication of the Signal Service, prepared by Mr J. P. Finley, and issued in 1882. These storms are not limited to any one month or season; but they are most frequent in summer, especially in the months of June, April, July, and May, and least so in the months of December and January. Of 600 tabulated by Mr Finley, occurring from 1794 to 1881, 112 were in June, 97 in April, 90 in July, 81 in May, and only 9 in December and 7 in January. They are most frequent in the afternoon, between noon and six o'clock; the hour in which the greatest number occurred was that from 5 to 6 P.M. The course of more than half of the 600 (310) was from south-west to north-east, and only 38 moved in the opposite direction. Only 46 had a course directed from the eastern side of the meridian towards the western. The width of the path of destruction varied from 40 to 10,000 feet, the average being 1085 feet. The velocity of progression of the storm-cloud, in 130 cases in which this item is given, varied from 12 to 60 miles per hour, the average being 30 miles. The time consumed by the tornado in passing any given point varied from 10 seconds to 30 minutes, the average of 50 occurrences being 6'52 minutes. The velocity of the wind within the cloud vortex was variously estimated at from 70 to 800 miles an hour. The whirling motion of the cloud was invariably from right to left. Of 600 tornadoes investigated, 184 were reported as being "unusually destructive." Of these 64 occurred within the States of Kansas, Illinois, Iowa, and Missouri, and this region, lying adjacent to the Mississippi river, seems to be that in which the conditions are most favourable to the development of these phenomena. There are also two areas—one in Georgia and one in New York—where tornadoes are more frequent than they are elsewhere in the eastern States. Of the destructiveness of these tornadoes some idea may be formed from the statement that in many of them buildings and everything else projecting from the surface are levelled to the ground, fragments of the materials thus uprooted being carried often to great distances. In the tornado of April 18, 1880, the effects of which were felt along a path more than a hundred miles in length through Illinois and Missouri, in one town over which it passed, 65 persons were killed, over 200 wounded, and more than 200 buildings were demolished. The loss of property in two counties of Missouri was over a million dollars.

The series of destructive storms which took place on the 19th of February 1884 is probably the most remarkable occurrence of this kind which has taken place in the United States since the country was settled by the whites. The loss of property was not less than \$3,000,000 to \$4,000,000, while 800 persons lost their lives, and about 2500 were wounded. From 10,000 to 15,000 were rendered homeless, as many as 10,000 buildings having been destroyed. Great quantities of live stock also perished. A central area of barometric depression moved between 7 A.M. of the 18th and 7 A.M. of the 19th from Fort Keogh to the vicinity of Chicago; at the same hour on the 20th it was about 150 miles north-west of Montreal. On the 19th, at 7 A.M., another extremely elongated area of barometric depression had been formed, extending almost north and south across the whole United States, and having its centre near Davenport, Iowa. Towards this centre the winds blew from north and south, the isotherms indicating very great contrasts of temperature between the areas of northerly and southerly winds, this condition of things being an invariable precursor of tornado development. The two centres of barometric disturbance were, as is commonly the case in occurrences of this kind, widely separated. At 3 P.M. of the 19th the centre of the north and south trending barometric depression was near Indianapolis, the contrasts of temperature remaining extreme, and violent winds developing themselves at various points south of Indianapolis, especially along the Ohio river from Cairo to Louisville, in the vicinity of Nashville, and in northern Alabama. At 11 P.M. of the same day the barometric trough had diminished somewhat in intensity, and the entire area of disturbance was passing rapidly off to the north-eastward. Between 3 P.M. and sundown the area devastated was chiefly in eastern Alabama and northern Georgia. Before 11 P.M. the destructive storms in North and South Carolina had reached their maximum violence; those in southern Virginia were most destructive about midnight. The Signal Service charts for the day indicate about thirty distinct areas of violent tornadoes, most of them between the eastern border of Alabama and the southern boundary of Virginia.

VEGETATION.

No portion of the United States attains so high a latitude that the forest growth should be necessarily dwarfed by the cold, or disappear altogether. The northern boundary is, however, practically nearly the limit beyond which valuable timber cannot be

expected. The portions of the United States where altitude is fatal to the growth of forest vegetation are insignificant as compared with the area of the whole country. The Appalachian ranges—which originally were densely forested from extreme north-east to extreme south-west, and which still continue to be so over a considerable portion of their extent—only rise at a very few points high enough to cause the forests to disappear. This is the case particularly with Mount Washington and the higher adjacent peaks, and with the summits of the most elevated part of the system in North Carolina. The Adirondacks are densely wooded, even almost to the highest summits. In the most elevated mountain-chains making up the Cordilleran system, want of moisture appears to co-operate with elevation in thinning out the forests on their flanks and causing them to disappear entirely on the highest ranges. The timber line on the most elevated peaks of Colorado reaches from 11,000 to about 11,500 feet,—the summits themselves rising from 2000 to 3000 feet higher. The Sierra Nevada is bare of forests in its highest portions. The high region about Mount Whitney is, where not snow-covered, nothing but an entirely bare mass of granite domes and needles. In the central part of the Sierra, in the vicinity of the Yosemite valley, forest vegetation is extremely scanty above 9000 feet, and the upper 3000 feet of the highest peaks is entirely bare of trees. If large areas of the United States are destitute of trees, and other regions but very poorly supplied, the chief cause of this is want of sufficient moisture.

In briefly indicating the nature and distribution of the forests of Appala-
the United States, we may begin with the Appalachian region, which here must be taken as embracing also the country to the forests. west and south-west, including the valleys of the Mississippi and Missouri, as far west as the western boundary of the State of Missouri, or about the 95th meridian, to the east of which lies, coincident with the region of generally abundant and everywhere sufficient rainfall, that portion of the United States which is almost everywhere densely forested, and the only portion which is so, with the exception of a comparatively narrow strip on the Pacific coast. Included within this densely-forested region of the Appalachian system and Mississippi valley there is quite a large area destitute of continuous forests,—the so-called "prairie region" (see below). The portion of the United States first settled by Europeans was, almost without exception, a densely-forested region, over which the aboriginal inhabitants roamed, without having interfered to any perceptible extent with the natural forest growth of the country. Their numbers were small, and their habitations were, almost without exception, either on or near the shores of the ocean and its bays and indentations, or along the river bottoms, in such places as were naturally grassed and not forested. This densely-forested region extends throughout the whole length of the Atlantic coast from Maine to Florida, west through the region of the Great Lakes to beyond Lake Superior, and to the south-west through Louisiana and for some distance into Texas. It differs from the densely-forested region of the Pacific in that it is essentially a region of deciduous or hardwood forests, while the latter is essentially one of coniferous trees; it differs from the forested region of the Rocky Mountains in that the latter is not only essentially a region of coniferous trees, but one where the forests do not by any means occupy all the area, neither do they approach in density or economic importance those of the eastern division of the country. Again, the forests of the east embrace a great variety of species, which, as a rule, are very much intermingled, and do not, unless quite exceptionally, occupy areas chiefly devoted to one species; while, on the other hand, the forests of the west—including both Rocky Mountain and Pacific coast divisions—exhibit a small number of species, considering the vast area embraced in the region; and these species are, in quite a number of instances, extraordinarily limited in their range, although there are cases in which one or two species have almost exclusive possession of very extensive regions. The eastern forested region, while continuous from north-east to south, south-west, and west, is of course marked by changes in the species corresponding with the changes in temperature between the extreme north-east and the extreme south. These changes, however, are almost without exception gradually made, and we pass almost imperceptibly from a northern to a southern forest. This condition is, in a measure, the consequence of the breadth and high elevation of the Appalachian system in its southern extension, along which elevated belt the northern aspect of the arboreal vegetation is prolonged into a region almost semi-tropical.

The following hardwood trees may be mentioned as being the most prominent and important in the forests of the eastern division of the country. The sugar-maple (*Acer saccharinum*), called also the hard and rock maple, ranges as far south as northern Alabama, but is of the most economical importance in New England and the region of the Great Lakes. On the southern shore of Lake Superior, in the higher portions of the country, on and near the divide between the waters flowing into the lake and those which descend to the Mississippi, the forest, over large areas, is almost exclusively

made up of this species, the "bird's-eye" variety—formerly much prized for cabinet work—being there abundant. The other species of maple of less importance are the soft maple (*A. dasycarpum*), having a wide range, and attaining its greatest development in the valley of the lower Ohio, and the red maple (*A. rubrum*), also ranging from New Brunswick westward to the Lake of the Woods and south to Texas, and being largest and most abundant in the central portion of the Mississippi valley. The oaks range over the entire eastern forested region from Maine to Florida, and west nearly as far as arboreal vegetation extends. The number of species is large. The white oak (*Q. alba*) ranges over nearly the whole forest region of the east, reaching its greatest development along the western portion of the Appalachian belt, and in the valley of the Ohio and its tributaries. The burr oak (*Q. macrocarpa*) has almost as wide a range as the white oak, extending farther west and north-west than any oak of the Atlantic forests; it forms, with the scarlet oak (*Q. coccinea*), the principal growth of the "oak-openings" in the prairie region. The red oak (*Q. rubra*) has also a wide range; it extends farther to the north than any other species. The jack oak or black jack (*Q. nigra*) is a small tree of little value except for fuel, but widely disseminated in the west and south-west of the eastern forest region, and forming with the post oak (*Q. obtusiloba*) the growth of the so-called "cross timbers" of Texas. The live oak (*Q. virens*) is an evergreen tree of considerable value, chiefly developed along the Gulf coast and through western Texas into the mountains of northern Mexico. The chestnut oak (*Q. prinus*) ranges through the Appalachian region, from Lake Champlain to northern Alabama, and west to central Kentucky and Tennessee. Its bark is used in preference to that of the other North American oaks in tanning. The ash is represented by several species. The white ash (*Fraxinus americana*) is of special value, and its range is very extensive, namely, east and west from Nova Scotia to Minnesota, and south-west to the extreme border of Texas. This species has its greatest development in the bottom lands of the lower Ohio valley. Towards the west and south-west it diminishes in size and importance, and is replaced to a considerable extent by the green ash (*F. viridis*). The range of the red ash (*F. pubescens*) is nearly as large as that of the white ash, except that it does not extend quite so far to the south-west. Its wood is less valuable. The chestnut (*Castanea vesca*, var. *americana*) is an important tree, with a wide range. The American chestnut is smaller and sweeter than the European. The species ranges from southern Maine west to Indiana, and south along the Appalachians to northern Alabama, attaining its greatest development along the flanks of the mountains in North Carolina. The birch is represented in the eastern forest region by several species. The white, canoe, or paper birch (*Betula papyracea*) reaches a higher latitude than any other tree of the American deciduous forest. It ranges south to the mountainous region of northern Pennsylvania, and west to British Columbia. The yellow or grey birch (*B. lutea*) is one of the largest and most valuable trees of the New England forest, ranging south along the higher portion of the Appalachians to North Carolina, and west to southern Minnesota. There are in the region several species belonging to the two genera of the *Juglandaceæ*, *Juglans* and *Carya*, which have a wide range, and are of importance both for their wood and for their fruit, and which also are among the most attractive ornaments of the forest. Prominent among these are the hickory (*Carya alba*), the butternut (*Juglans cinerea*), the black walnut (*J. nigra*), and the pecan (*C. olivæformis*). The pecan does not occur to the north-west of Indiana, has its greatest development in the rich bottom lands of Arkansas, and is the largest and most important tree of western Texas. The butternut occurs in New England, but is by no means an abundant tree in that region; farther west, especially in the valley of the Ohio, it attains its maximum development. The black walnut is hardly known in New England, unless on its extreme western border; but south-westward along the Appalachians and west to the Mississippi it is a tree of great value and importance. It attains its maximum development on the western slope of the southern portion of the Appalachian range and thence to Arkansas. Hardly any other wood is ever used for gunstocks. The American elm (*U. americana*) has a wide range, extending from southern Newfoundland to Texas and west to central Nebraska. This species is especially the tree of the river bottoms, and specimens occurring isolated in natural meadows often attain great size. The rock or white elm (*U. racemosa*) is a tree hardly occurring in New England, but largely developed in the region of the Great Lakes, west to north-eastern Iowa, and south to central Kentucky. Its wood is considerably denser than that of *U. americana*. The beech (*Fagus ferruginea*) occurs through nearly the whole of the eastern forest region, ranging from Nova Scotia south and south-west to Florida and Texas, and west to Missouri. The linden, lime, bass-wood, or white-wood (*Tilia americana*) is a tree of wide range, occurring more and more abundantly as we go west from New England through the region south of the Great Lakes into the Ohio valley, and found south along the Appalachians to Georgia. It has its maximum development towards the west and south-west

in the rich bottom-lands. The tulip tree (*Liriodendron tulipifera*), called also yellow poplar and white-wood, is one of the largest and most beautiful trees of the eastern forest region. It is rare in New England, but has its maximum development from New Jersey south along the slopes of the Appalachians to Tennessee and North Carolina, and west in the Ohio valley. The genus *Magnolia* is represented by several species, two of which are of importance, especially for the great beauty of the tree and its flowers. These—*M. glauca* and *M. grandiflora*—like the other species of the magnolia, are pretty closely limited to the Atlantic coast and Gulf region, and the lower portion of the Mississippi valley. *M. glauca*, which has a variety of names, among which those of sweet bay and white laurel are most common, is found over a small area on Cape Ann in Massachusetts, and in no other place in New England,—its range being from New Jersey southward, chiefly along the coast to Florida, and west to Arkansas and Texas. *M. grandiflora*, called the big laurel or the bull bay, an evergreen, and one of the finest trees of the region, is pretty closely limited to the southern and south-western coast, ranging from North Carolina south to Tampa Bay, westward to south-western Arkansas, and along the Texas coast to the valley of the Brazos. There are two trees known familiarly as the locust which are of considerable importance. One is the *Robinia Pseudacacia*, commonly called either simply the locust or the yellow locust; the other is *Gleditsia triacanthos*, to which the popular names honey locust, acacia, sweet locust, and black locust are given. The former occurs naturally in the Appalachians from Pennsylvania to Georgia, reaching its maximum development on the western slopes of the mountains of West Virginia, but has been introduced and cultivated over the whole region east of the Rocky Mountains, wherever trees can be made to grow. This tree, however, over an extensive portion of the region where it was formerly cultivated has been exterminated by the attacks of the "locust borer" (*Cyrtene picta*). The other locust, the three-thorned acacia, ranges from Pennsylvania, along the western flanks of the Appalachians, south as far as Florida, south-west through northern Alabama and Mississippi to Texas, and west from Pennsylvania through southern Michigan to eastern Kansas. It is the characteristic tree of the "barrens" of middle Kentucky and Tennessee, and attains its maximum development in the lower Ohio bottom-lands. It is widely cultivated throughout the region east of the Appalachians for shade and ornament, and for hedges. There are certain trees and shrubs in the eastern forest region of little or no economical importance, but which, especially when in flower, are highly ornamental. Of these only a few can be mentioned: the mountain ash (*Pyrus americana*), ranging over nearly the whole region, and much cultivated as an ornamental tree on account of the beauty of its fruit, of dark reddish or scarlet colour, and remaining long upon the branches; the sumach (*Rhus glabra*), a handsome shrub, from 4 to 10 feet in height and very striking both for foliage and fruit, and a very characteristic feature of the New England landscape, as seen along the borders of the forests and by the sides of country roads; the mountain laurel (*Kalmia latifolia*), covering extensive areas of half-cleared forests in the hilly regions and very conspicuous at the flowering season, June and July, one of the most beautiful of all the characteristic native American shrubs; the dog-wood or cornel (*Cornus alternifolia*), a beautiful shrub, rising occasionally to sufficient height to be called a tree, ranging from the St Lawrence to Alabama, and in certain regions, especially in parts of New Jersey and Pennsylvania, very conspicuous at the time of its flowering, the landscape from a distance looking as if it had been snowed upon. The red-bud (*Cercis canadensis*), a small tree, is a conspicuous feature of the forest in the extreme south-west, especially in southern Arkansas, the Indian Territory, and eastern Texas.

Although the forest vegetation of the eastern region is essentially deciduous in character, coniferous trees are widely spread over the whole country from Maine to the southern border of Georgia. The genus *Pinus* is by far the most widely distributed and most interesting of the conifers. First in value is the white pine (*P. strobus*), a northern tree, having its maximum development in the region of the Great Lakes, ranging from Maine west to Lake Superior, and south-west along the Appalachians to Georgia, and attaining a height greater than that of any other species in the eastern forest region, namely, somewhat less than half that of the tallest trees in the Pacific coast belt. The most important pineries of the eastern States are in Maine, where this species occurs scattered through the deciduous forests, and where the most easily accessible trees of large size have already been pretty well thinned out; Michigan and Wisconsin are the chief pine-producing States of the western and north-western region. Saginaw Bay, on Lake Huron, may perhaps be designated as the headquarters of the north-western pine lumber industry. The somewhat less valuable southern pine (*P. palustris*), called also hard, yellow, long-leaved, and Georgia pine, is, in contrast with the white pine, decidedly a southern species, ranging from southern Virginia south to Florida, and south-west through the Gulf States to the valley of the Red River in Louisiana and that of the Trinity in Texas. It occurs over ex-

tensive areas almost entirely unmingled with other species, occupying the so-called "pine barren" zone of the southern Atlantic States, of especial importance in North and South Carolina and Georgia. The wood of this tree is heavy, hard, and tough. It furnishes almost all the tar, pitch, rosin, and spirits of turpentine used in the United States. Another important pine, *P. mitis*, the yellow, short-leaved, or bull pine, ranges from Staten Island south to western Florida, through the Gulf States and Tennessee to eastern Texas, and west of the Mississippi into Kansas and Missouri, reaching its greatest development in western Louisiana, southern Arkansas, and eastern Texas. It is an important tree in the southwest, and west of the Mississippi, and among the yellow pines only inferior in value to *P. palustris*. Another important conifer, next to *Pinus palustris* the most characteristic tree of the south-eastern coast timber belt, is the cypress (*Taxodium distichum*), which ranges from Delaware south along the coast to Florida, and south-west to Texas, forming extensive forests in the southern Atlantic and Gulf States, and also extending up the Mississippi to southern Illinois and Indiana. The cypress is a marked feature in the swamp country which extends along the coast from Virginia through North and South Carolina, of which the Great Dismal Swamp, on the borders of Virginia and North Carolina, may be taken as the type. These swamps are locally known through the region where they occur as "dismals" or "pocosins." The largest continuous area of swamp in North Carolina lies between Albemarle and Pamlico Sounds, covering an area of nearly 8000 square miles. The prevalent growth of the best swamp lands is the black gum (*Nyssa sylvatica*), tulip tree or poplar, cypress, ash, and maple, the proportion of cypress increasing as the soil becomes more peaty. These so-called swamps—in large part at least—differ essentially from what is usually called a swamp, being considerably elevated above the adjacent streams; they are, in fact, immense accumulations of decaying vegetation, often peaty in character with more or less fine sand intermingled, and with a very considerable variety of forest vegetation. Portions of these swampy areas have been successfully drained and brought under cultivation; other portions have resisted all attempts of the kind, although there has been a large amount of money expended in endeavouring to reclaim them. Besides the pines, there are to be mentioned here the spruces, firs, larches, and cedars, which together form a marked zone of vegetation decidedly northern in character, extending through the northern part of New England, through Canada to the Upper Lakes, and far to the north and north-west, where it unites with the forest belt of the Rocky Mountains, in almost the extreme northerly extension of this range within the United States. The northern forms of coniferous trees also occur in the highest portion of the Appalachians as far south as North Carolina, and are found along the most elevated ridges of the Rocky Mountain range, from the extreme north through to Arizona and New Mexico, and along the culminating portion of the Sierra Nevada nearly to the southern border of California. One of the most characteristic of these northern trees is the balsam fir (*Abies balsamea*), which ranges from Labrador north-west to the base of the Rocky Mountains, occurring in central Michigan, along the north shore of Lake Superior, and in the more elevated and damper portions of the Appalachians south to Virginia. This is the tree which produces the "Canada balsam." There are two species of spruce which have about the same range as the species last mentioned, the black spruce (*Picea nigra*) and the white spruce (*P. alba*). The hemlock (*Abies canadensis*) is another very characteristic tree of the northern forests, where perhaps more than any other tree it sometimes occurs in "groves" or over areas of considerable size to the almost entire exclusion of other species. It is met with along the higher Appalachian ranges, south as far as Alabama; and, although it is much more abundant at the north than at the south, the largest specimens of it are said to be found in the high mountains of North Carolina. The bark of this tree is the principal material used in the northern States in tanning. The larch (*Larix americana*), much more commonly called the tamarack or hackmatack, is another very characteristic northern species, although, like most of the others, ranging to a considerable distance south along the higher regions of the Appalachians. Swampy areas, over which water stands during a considerable part of the summer, are often covered with a sparse growth of this species, to the almost entire exclusion of other trees. These swamps, which are especially common in portions of the upper peninsula of Michigan, are usually known as tamarack swamps. The white cedar or arbor vitae (*Thuja occidentalis*) is a very common species in the north, and is much cultivated as a hedge and ornamental tree. Large swampy areas in the north, especially in the region south of Lake Superior, are covered with a gnarled and tangled growth of this species, and are called by the English-speaking population "cedar swamps," and by the French *voyageurs* "savanes." In the farthest north-western regions of the United States, as, for instance, on Isle Royale and the adjacent shore and islands of Lake Superior, the dwarfed and tangled growth of the characteristic northern conifers makes travelling difficult and vexatious. It is sometimes, for long stretches, almost impossible to get over the ground except

by crawling on hands and knees. The white cedar (*Chamaecyparis sphaerocarpa*, more commonly known as *Cupressus thyoides*) is a tree pretty closely limited to the Atlantic and Gulf coast region, having its maximum development in the southern Atlantic States. It is one of the characteristic trees of the southern swampy belt.

Passing to the consideration of the western or Cordilleran side, Forest we begin with the narrow, but in part densely forested, belt of the Pacific coast. In this connexion notice will be taken of the distribution of the forests of the Rocky Mountains; for, although the two regions are separated over several degrees of latitude by the intervening region of the Great Basin, where forests are extremely scantily distributed, there are many points of resemblance between them, especially in their northern extension. In the size and density of growth of some of the species, and in the grandeur of the forest scenery generally, portions of the Pacific coast belt surpass anything else that the country has to offer. This region of dense forest growth begins on the western slope of the Sierra Nevada, at the southern extremity of the range, continuing north along that slope into Oregon and Washington Territory, where, in the region adjacent to Puget Sound, the forests are most remarkable for their density, as well as for the size and elevation of the individual trees. The most widely distributed and most valuable of the trees of this belt is the Douglas fir (*Pseudotsuga Douglasii*), which ranges from British Columbia south through the Coast mountains, and along the western slope of the Sierra Nevada to Arizona, and south-east along the Rocky Mountains through Montana, Wyoming, and Colorado, but not through the Great Basin. It often forms extensive forests, especially in the northern region, where it attains its maximum development. Its wood is extensively used on the Pacific coast, the headquarters from which it is supplied being the region adjacent to Puget Sound, where it grows to twice or three times the height it has in the Rocky Mountains. The yellow pine (*Pinus ponderosa*) ranges from British Columbia south along the Cascades and Sierra Nevada to Mexico, and occurs, irregularly distributed, along the Rocky Mountains from Montana, where it is quite abundant, to Arizona. For size and height this species, as well as the Douglas fir, is remarkable. Its wood is variable in character, but is largely used where a better quality cannot be obtained. The sugar pine (*P. Lambertiana*) occurs in abundance on the western flank of the Cascades and the Sierra Nevada, and is especially well developed in the central portion of the latter. It is one of the most conspicuous of the species which make up the grand forests of that part of the Sierra which lies at an altitude of from 2000 to 7000 feet above the sea. The digger pine (*P. Sabiniana*) is the characteristic tree of the foot-hills of the Sierra Nevada. It is remarkable for the large size of its cones, the seeds of which were formerly an important article of food for the aborigines. A characteristic tree of the Californian Coast ranges, similar in many respects to *P. Sabiniana*, and also having large and beautiful cones with very long, sharp, recurved points, is *P. Coulteri*. The wood of these two species is of little value except for fuel. Other Coast range pines of interest are—the Monterey pine (*P. insignis*), a tree peculiar to the sea coast, from Pescadero south to San Simeon Bay, and the Obispo pine (*P. muricata*), limited to the Coast ranges, from Mendocino south to San Luis Obispo. The pines of the high mountain region are—*P. monticola*, occurring in the Sierra Nevada at an altitude of from 7000 to 10,000 feet, and common in the northern part of the Rocky Mountains, as well as in the Cascade range, and in portions of the mountainous region of Idaho, where it is an important and valuable tree, and is sometimes called the white pine; *P. flexilis*, a tree occurring in limited numbers in the highest parts of the southern High Sierras of California, and here and there south along the higher portions of the Rocky Mountain ranges and also in the Great Basin, from Montana south to Arizona; *P. albicaulis*, by some considered a variety of *P. flexilis*, by others a distinct species, and having a similar range with that species; *P. Balfouriana*, and *P. aristata*, a variety of *P. Balfouriana*, found about Mount Shasta, at from 5000 to 8000 feet in altitude, and around the base of Mount Whitney, also occurring in the very highest portions of the Rocky Mountains, and in parts of the Great Basin south to Arizona; *P. Jeffreyi*, by some considered a variety of *P. ponderosa*, reaching its maximum development in the Sierra Nevada, and occurring throughout the whole length of that range at high elevations; *P. concolor* and *P. Murrayana* (the latter often confounded with the former, and by most botanists considered as a variety of it), a common species on the High Sierra at from 8000 to 9000 feet in altitude, extending into Oregon and through the Rocky Mountains south to northern Arizona. Two trees, limited in their occurrence to California, and of great interest on account of their size and beauty, belong to the genus *Sequoia*—the redwood (*S. sempervirens*) and the big tree (*S. gigantea*). The redwood occurs quite close to the coast, in a narrow almost uninterrupted belt, from a point in the Santa Lucia range about fifty miles south of Monterey to very near the north line of the State. North of Russian river this tree forms an almost unbroken forest, extremely grand in character, individual trees rising to nearly 300

feet in height. The big tree occurs on the western slope of the Sierra in somewhat isolated groves or patches always intermingled with other trees, and not forming forests by itself as the redwood does. Its range is from 36° to a little beyond 38° N. lat., there being nine groves, the largest of which is about thirty miles north-north-east of Visalia, on the tributaries of King's and Kaweah rivers. The groves in Mariposa and Calaveras counties are those most visited by tourists, and in the latter is the tallest of these trees, and the tallest tree on the American continent, so far as known (325 feet). Another conifer of much interest from its beauty and its very limited range is the Monterey cypress (*Cupressus macrocarpa*), a species occurring only on Cypress Point, near Monterey. The Port Orford cedar (*Chamaecyparis Lawsoniana*), a strictly Pacific Coast species, ranging from Coos Bay in Oregon into northern California, is a large and valuable tree, with an odoriferous, highly resinous wood. The white cedar of the Pacific coast (*Libocedrus decurrens*, called by some botanists *Thuja gigantea*) is also a Pacific Coast species, ranging from the Santiam river in Oregon south through the Coast ranges as far as Mount San Bernardino. The *Thuja gigantea* proper, or red or canoe cedar, is another Pacific Coast range tree; but, unlike the two species last mentioned, it extends its range into the northern Rocky Mountain region. It is a large tree, which has its maximum development in the Coast ranges of Washington Territory and Oregon.

The deciduous trees of the Sierra Nevada and the Cascade range, as well as of the Pacific Coast ranges from California north to the boundary line, are of comparatively little importance. There are several species of oak, but of little value,—among them being the Coast live oak (*Q. agrifolia*), the largest and most generally distributed oak in the south-western part of California; the black oak (*Q. Kelloggii*), ranging along the coast mountains of Oregon, and the most characteristic hardwood tree of the western slope of the Sierra; and the chestnut oak (*Q. densiflora*), occurring in the Coast ranges from Oregon to central California. An evergreen tree, very characteristic of the coast ranges of Oregon and California, and very ornamental, is the California laurel (*Umbellularia californica*), of which the wood is hard and strong, and of a very pleasing light-brown mottled colour. The tree called the madroña or madroño (*Arbutus Menziesii*) occurs from British Columbia south through the Coast ranges to the Santa Lucia Mountains, and is a very characteristic tree of the region, with its red bark and beautiful glossy foliage. The wood is used in the manufacture of gunpowder, and the bark to some extent in tanning.

In the area included between the two heavily-timbered regions described above, or between the summit of the Sierra Nevada and Cascade range and the western border of the great eastern forest region, the paucity of rainfall corresponds to paucity or almost entire absence of forests over much the larger portion. We may here distinguish, first, the Rocky Mountain region; then the Great Basin and the plateaus north and south of it; then the "Plains," or the nearly level country lying east of the base of the Rocky Mountains; and, finally, the "Prairie" region, or that portion of the scantily timbered area which for the most part lies enclosed within the eastern forested belt, and where other causes than the absence of moisture have operated to bring about the growth of a peculiar vegetation.

The Rocky Mountain belt is not destitute of forests, but these are very irregularly scattered over the surface, and the species are few in number, chiefly belonging to coniferous genera, and of little economic value. The species of conifers have been already mentioned, and their range indicated in speaking of the forests of the Sierra Nevada and Cascade range. Few forests in the Rocky Mountains at all compare in density or in the size of the individual trees with those of the Sierra and the Cascade range. What trees there are usually grow most densely in the moist places at the foot of the ranges, where the streams debouch from them, in the ravines and gorges, and on the lower slopes. By far the most common deciduous tree throughout this region is the aspen (*Populus tremuloides*), often called cottonwood and sometimes poplar, which most commonly springs up, forming dense thickets, throughout the Rocky Mountains, wherever the coniferous forest has been burned off. It ranges from Newfoundland to Arizona, and is the most widely distributed of North American trees, and highly characteristic of northern and elevated regions. In various portions of the Rocky Mountains there are scattered oaks. The scrub oak (*Q. undulata*, var. *Gambelii*) occurs in some quantity on the mountains of southern New Mexico and Arizona, and is also found in Colorado and along the Wahsatch range. The black oak (*Q. Emoryi*), the white oak (*Q. grisea*), and a few other species are found here and there in the southern part of the Rocky Mountains, as also in Arizona, and ranging south into Mexico. The most densely forested portions of the Rocky Mountains are the extreme northern in north-western Montana, the north-west corner of Wyoming, the higher part of Colorado, the eastern slope of the range in New Mexico, and the higher portions of Arizona.

Enclosed between the densely-forested Pacific belt and the

poorly-timbered region of the Rocky Mountains is an extensive Forests area, including the northern and southern plateaus and the Great of the Basin, which practically is nearly destitute of trees. The coniferous Great species occurring in the Rocky Mountains are found here and Basin. there along the moister tracts of the higher ranges in the Great Basin, especially in its eastern and higher portion, but by far the larger part of the slopes and nearly all the valleys are treeless, being chiefly occupied by the well-known "sage-brush" (*Artemisia tridentata*), which covers many thousands of square miles, especially in Nevada and Utah. Two trees are, however, very characteristic of the Great Basin, especially of its western portion—the juniper (*Juniperus occidentalis*) and the piñon or nut pine (*Pinus monophylla*). These two species, usually much dwarfed in size and scrubby in appearance, are almost the only trees of western and central Nevada, where they occur hidden away in the cañons. Everywhere in a wide sweep adjacent to the mining districts all this vegetation has been completely cleared away.

An order of plants peculiarly American, and characterizing in a Vegeta- most marked manner the hot dry region adjacent to the lower tion of Colorado, is that of the *Cactaceæ*. The cactus ranges from the the extreme north of the plateau region to the extreme south, but its Southern most abundant and striking development takes place in southern Plateau. Nevada, southern California, and in general the region adjacent to the Mexican boundary line. The so-called prickly pear (*Opuntia*) is the cactus family which has the widest range, being found from the upper Missouri through the Great Basin to Arizona. It has many species, that which ranges farthest north being *O. missouriensis*. The genera *Mamillaria*, *Echinocactus*, and *Cereus* are found in various localities in the Great Basin, as well as in southern California, in portions of which region, as well as in lower California and Arizona, there are large areas where various kinds of cactus form almost the exclusive vegetation, often rising to such a height as to be properly called trees; the loftiest of all is the singularly striking *Cereus giganteus*. Mingled with them are yuccas (called the "Spanish bayonet"), mezquites (*Algarobia glandulosa*), and the creosote bush (*Larrea mexicana*), which are among the most abundant and characteristic plants of this region.

The vast area extending east from the base of the Rocky Mountains "The to near the 95th meridian is the district universally known as "the Plains." Plains," and one not at all to be confounded with the "Prairies," which are almost entirely included within a region of dense forests, and over which the partial absence of trees is due to a cause entirely different from that which has made the plains the home of the grasses and not of trees. The transition from the forested region of the east to the region of the plains is, almost without exception, coincident with the diminution in the precipitation, which as we proceed westward goes on rapidly, and, on the whole, pretty regularly. Thus Dakota, between 97° and 104° W. long., is practically destitute of timber, except in its river bottoms and the small territory between the north and south forks of the Cheyenne, the region of the Black Hills. In Minnesota, which lies east of 97°, only the north-eastern portion, especially that adjacent to Lake Superior, is heavily timbered. The south-western corner of the State, embracing about one-third of its area, and the area west of the 96th meridian, are classed in the census report as having less than two cords of wood to the acre. Nebraska and Kansas, still farther south, are almost destitute of forests. In Nebraska only a narrow strip along the Missouri, near the meridian of 96°, is given as having from one to two cords of wood per acre. The heavy forest growth of the Mississippi basin just reaches the extreme south-eastern corner of Kansas. North of this, and along the eastern border of the State, there is a belt of from thirty to a hundred miles in width in which there is valuable timber on the borders of the streams. West of 97° W. long. the trees are confined to the immediate banks of the large streams, and are small and of little value. West of 99° we find the typical vegetation of the plains, with only a few small stunted willows and cottonwoods scattered at wide intervals along the streams. The yearly isohyetal of 26 inches forms a limit beyond which arboreal vegetation is almost entirely absent, while in going east there is little of value until we reach the belt in which the rainfall is over 32 inches. The same may be said of the Indian Territory and Texas, the bending of the isohyetal curves to the west as we approach the Gulf of Mexico being, however, as might be expected, accompanied by a corresponding extension of the forest belt in that direction. Thus, in Texas, the limit of what may be designated as the well-timbered region lies between 96° and 97°, while the line marking the entire disappearance of the forests may be placed somewhere between 99° and 100°, and pretty closely adjacent to the isohyetal of 26 inches.

The French word "prairie," a meadow or grassy plain, was Prairie employed by Hennepin about 1680, in his excellent description region. of the prairies of Illinois. The word has become current in the Mississippi valley, and still farther west. In the northern portion of the Rocky Mountains the small grassy areas adjacent to the streams and surrounded by mountains are called "prairies," while farther south they are known as "parks," the still smaller

areas being frequently denominated "holes." In general, however, the term prairie is used to designate tracts of land nearly or quite destitute of forests, or over which the trees are, as a general rule, limited to the "bluffs"—the more or less precipitous slopes which separate the upland, or prairie proper, from the river bottom—which treeless areas occur in the midst of a well-forested country. Illinois is *par excellence* the Prairie State, and may be considered the centre of the prairie region, the adjacent States, on all sides, having more or less prairie and also areas of dense forest.

All through the prairie region the precipitation is abundant and pretty equally distributed through the year. The vicinity of Chicago, a typical prairie region, comes within the isohyetal of 44 inches and upwards, and the same is true of a part of the treeless region of Iowa. Large areas in the more southern States—Arkansas, Alabama, Mississippi, and Louisiana—are also prairies, portions of which are entirely destitute of forests, while others have small "clumps" of trees sparsely scattered over their surface. This is in a region of the largest rainfall, that of 56 inches and upwards. The cause of the absence of trees on the prairies is the physical character of the soil, and especially its exceeding fineness, which is prejudicial to the growth of anything but a superficial vegetation, the smallness of the particles of soil being an insuperable barrier to the necessary access of air to the roots of a deeply-rooted vegetation. Wherever in the midst of the extraordinarily fine soil of the prairies coarse or gravelly patches exist, there dense forests occur. The theory that fineness of soil is fatal to tree growth finds its most remarkable support in the fact that in southeastern Russia the limits of the "black earth" and the treeless region are almost exactly identical, and not at all in harmony with the position of the isohyetal lines. The black soil of Russia is an earth of exceeding fineness—so fine indeed that it is with the greatest difficulty that the air can penetrate it so as to oxidize the organic matter which it contains,—the essential cause (in the opinion of the present writer) of its dark colour. The peculiar mode of decay of the organic matter in such fine soils seems analogous to that by which vegetation has been turned into coal or lignite when so buried under detrital material as to greatly impede the access of the air. It is now easy to see why plains are likelier than mountain slopes to be treeless, it being towards the plains that the finer particles of the material which is abraded from the higher regions are being constantly carried. The more distant the region from the mountains and the broader its area the more likely it is that a considerable portion of it will be covered with fine detritus, whether this be of subaerial origin or deposited at the bottom of the sea. The exceedingly fine soil of the typical prairie region consists, in large part, of the residual material left after the removal, by percolation of the rain and other atmospheric agencies, of the calcareous portion of the undisturbed stratified deposits, chiefly of Palæozoic age, which underlie so large a portion of the Mississippi valley. The finer portions of the formations of more recent age in the Gulf States have also, over considerable areas, remained treeless. There are in various parts of the country beds of lakes which have disappeared in consequence of their very slow filling up with fine sediment, and these are not occupied by the forest, although surrounded by the densest arboreal growth.

Economic importance of the forests.

The principal use of the forests of the United States is for fuel; and there is no part of the settled portion of the country where the consumption for this purpose is not of some importance. In the middle and northern Atlantic States coal is the chief fuel in the cities and large towns, and the almost exclusive fuel of the larger cities on important lines of communication, but supplemented, to a greater or less extent, by wood. But in the country, on the farms, and in the small towns wood is almost exclusively used, except on the coal-fields or in their immediate vicinity. In the coal-producing States of Illinois and Iowa, where forests are limited to certain areas, and in Nebraska and Kansas, which have coal of inferior quality and where forests are still scarcer than they are in Illinois and Iowa, coal is the dominating fuel. The same is the case in certain parts of Missouri. In all the States south of Virginia and Kentucky wood is almost the exclusive fuel, except in a few of the very largest towns. Wood is also almost exclusively the material of which houses and barns are built over the whole United States, the exceptions being the larger cities (chiefly of brick, with some stone), the business portions of the towns of second rank, and occasional important buildings in towns of the third rank. The other uses of wood are obvious. The following figures given by the census of 1880 relate to the manufacture of sawn lumber:—establishments, 25,708; capital, \$181,186,122; average hands employed, 147,956; feet of lumber produced, 18,091,856,000; laths, 1,761,788,000; shingles, 5,555,046,000; staves, 1,248,226,000; sets headings, 146,523,000; feet of bobbin and spool stock, 34,076,000; total value of specified products, \$230,685,061; value of other products, \$2,682,668; total value, \$233,367,729. The consumption of wood for domestic fuel is given in 1880 as amounting to 140,537,439 cords, with an estimated value of \$306,950,040, and the total consumption of wood as fuel as 145,778,137 cords, valued at \$321,962,373.

MINERAL RESOURCES.

In 1619 the erection of "works" for smelting the ores of iron History was begun at Falling Creek, near Jamestown, Va., and iron appears to have been made in 1620; but the enterprise was stopped by a sketch of general massacre of the settlers in that region. In 1643 the business of smelting and manufacturing iron was again begun at Lynn, Mass., where it was successfully carried on, at least up to 1671, furnishing most of the iron used in the colony. From the middle of the 17th century the smelting of this metal began to be of importance in the vicinity of Massachusetts Bay, and by the close of the century there had been a large number of iron-works established in that colony, which, for a century after its settlement, was the chief seat of the iron manufacture in America, the bog ores, taken from the bottoms of the ponds, being chiefly employed. Early in the 18th century the industry began to extend itself over New England, and into New York and New Jersey, the German bloomery or forge being employed for reducing the ore directly to bar iron, and by the middle of that century it had taken a pretty firm hold in the Atlantic States. About 1789 there were fourteen furnaces and thirty-four forges in operation in Pennsylvania. Before the separation of the colonies from the mother country took place the manufacture of iron had been extended through all of them, with the possible exception of Georgia. As early as 1718 iron (both pig and bar) began to be sent to Great Britain, the only country to which the export was permitted, the annual amount between 1730 and 1775 varying ordinarily between 2000 and 3000 tons, but in one year (1771) rising to between 7000 and 8000 tons.¹

So far as known, the first metal, other than iron, mined by the whites within the territory of the United States was copper.² The first company began work about 1709, at Simsbury, Conn. The ore obtained there and in New Jersey seems to have been mostly shipped to England. A few years later attempts were made to work mines of lead and cobalt in Connecticut and Massachusetts, but none of these enterprises seem to have been conducted with much vigour or to have met with any success. The first metal, other than iron, mined and smelted on any scale of importance was lead. The ore of this metal—galena—occurring in considerable quantity, and in many localities, on or near the Mississippi, and being easily smelted by the roughest possible methods, was made use of at an early date. While this region—then called Louisiana—was in possession of the Spanish, some mines were opened and worked, although in a very rude manner, the ore being taken out from mere pits and smelted on log-heaps. In 1774 Julien Dubuque began operations in the region of the upper Mississippi, at the place where is now the flourishing city which bears his name; but no real development of the mining interest took place in that region until half a century later.

The first mining excitement of the United States dates back to the discovery of gold by the whites in the southern States, along the eastern border of the Appalachian range, in Virginia, and in North and South Carolina. The existence of gold in that region had been long known to the aboriginal inhabitants, but no attention was paid to this by the whites, until about the beginning of the present century, when nuggets were found, one of which weighed 28 lb. From 1824 the search for gold continued, and by 1829 the business had become important, and was attended with no little excitement. In 1833 and 1834 the amount annually obtained had risen to fully a million of dollars. A rapid development of the lead mines of the West, both in Missouri and on the upper Mississippi in the region where Iowa, Wisconsin, and Illinois adjoin one another, took place during the first quarter of the present century, and as early as 1826 or 1827 the amount of this metal obtained had risen to nearly 10,000 tons a year. By this time the make of iron had also become important, the production for 1828 being estimated at 130,000 tons.

In 1820 the first cargo of anthracite coal was shipped to Philadelphia. From 1830 the increase in the production was very rapid, and in 1841 the annual shipments from the Pennsylvania anthracite region had nearly reached 1,000,000 tons, the output of iron at that time being estimated at about 300,000 tons. The development of the coal and iron interests, and the increasing importance of the gold product of the Appalachian auriferous belt, and also of the lead product of the Mississippi valley, led to a more general and decided interest in geology and mining; and about 1830 geological surveys of several of the Atlantic States were begun, and more systematic explorations for the ores of the metals, as well as for coal, were carried on over all parts of the country then open to settlement. An important step was taken in 1844, when a cession of the region on the south shore of Lake Superior was obtained from the Chippeway Indians. Here explorations for copper immediately commenced, and for the first time in the United States the business of mining for the metals began to be developed on an extensive scale, with suitable appliances, and with financial success.

¹ Throughout this article, by "ton" is understood the ton of 2240 lb, unless the contrary is expressly stated.

² This metal had also been extensively mined in the Lake Superior region long before the first visit of the English.

An event of still greater importance took place almost immediately after the value of the copper region in question had been fully ascertained. This was the demonstration of the fact that gold existed in large quantities along the western slope of the Sierra Nevada of California, a region which had just come into the possession of the United States. The discovery led to extraordinary excitement throughout the older States, and to an immigration from all parts of the world on an unprecedented scale. The production of this precious metal rose almost at once to figures far surpassing anything definitely known in history. In five years from the discovery of gold at Coloma on the American river, the yield from the auriferous belt of the Sierra Nevada had risen to an amount estimated at between sixty-five and seventy millions of dollars a year, or five times as much as the total production of this metal throughout the world at the beginning of the century. This rapid development led to a great mining excitement in the eastern States, as a result of which new veins and deposits of various metals were discovered, and many which had been previously worked to a limited extent and then abandoned were again taken up. This excitement was at its height in 1852 and 1853, but soon slackened as it began to be shown by the results of actual working that, while "indications" of the valuable ores of the metals are very abundant in the Appalachian belt, the localities where these ores occur in sufficient abundance to be profitably worked are comparatively few.

Mining
indus-
tries
about
1850.

The following details show the development of the mineral resources of the country at the middle of the present century. In 1850 the shipments of anthracite amounted to nearly 3,500,000 tons; those of Cumberland or semi-bituminous coal were about 200,000 tons. The yearly production of pig iron had risen to between 500,000 and 600,000 tons. The annual yield of gold in the Appalachian belt had fallen off to about \$500,000 in value, that of California had risen to \$36,000,000, and was rapidly approaching the epoch of its culmination (1851-1853). No silver was obtained in the country, except what was separated from the native gold, that mined in California containing usually from 8 to 10 per cent. of the less valuable metal. The ore of mercury had been discovered in California before the epoch of the gold excitement, and at New Almaden, about 100 miles south of San Francisco, was being extensively and successfully worked, the yield of this metal in the year 1850-51 being nearly 2,000,000 lb. At this time the copper mines of Lake Superior were being successfully developed, and nearly 600 tons of metallic copper were produced in 1850. At many points in the Appalachian belt attempts had been made to work mines of copper and lead, but with no considerable success. About the middle of the century extensive works were erected at Newark for the manufacture of the oxide of zinc for paint; about 1100 tons were produced in 1852. The extent and value of the deposits of zinc ore in the Saucon valley, Pennsylvania, had also just become known in 1850. The lead production of the Missouri mines had for some years been nearly stationary, or had declined slightly from its former importance; while that of the upper Mississippi region had, in the years just previous to 1850, risen to from 20,000 to 25,000 tons a year, but was gradually declining, having in 1850 sunk to a little less than 18,000 tons.

Coal.

Coal.—Coal exists in the United States in large quantity in each of its important varieties,—hard coal, or anthracite; soft or bituminous coal; and lignite, or brown coal. Semi-bituminous coal, which stands midway between hard and soft coal, is also an article of importance, being especially well adapted for blacksmiths' use, and also for ocean-going steamers. Geologically, the anthracite, semi-bituminous, and bituminous coals nearly all belong to the same formation, the Carboniferous *par excellence*. All the coal of the Appalachian region and Central Valley is of this geological age, excepting the small field near Richmond, Va., and two in North Carolina, the Deep River and Dan River fields, which are of Mesozoic age. That of Richmond was the first coal-field worked in the United States; but it is no longer of any importance. The North Carolina Mesozoic areas have never been developed to any extent. All the Cordilleran coal and that at the eastern base of the Rocky Mountains is either Tertiary or belongs to the very uppermost portion of the Cretaceous. Some of it is decidedly lignite, and is so called by the people who use it; but most of it, although of so recent geological age, is called coal, and, in point of fact, does not differ essentially from Palæozoic coal in external appearance. The area underlain by the Coal-measures in the United States is very large.

The areas of the various coal-fields are, in round numbers, as follows:—Rhode Island, 500 square miles; Appalachian, 59,000; Central (Illinois, Indiana, Kentucky), 47,000; Western (Missouri, Iowa, Kansas, Arkansas, Texas), 78,000; Michigan, 6700; total, 191,200. Of these fields the Appalachian is, and is likely long to remain, by far the most valuable. Those of Rhode Island and Michigan are practically of very little importance. Different portions of the fields are of very different value, as respects quality and quantity of coal, and portions of them do not contain coal-beds of sufficient thickness or of good enough quality to be worked with profit.

The following table (VI.) shows the amount of coal produced in the several States and Territories (not including the local and colliery consumption), and the value at the mines in 1885:—

	Tons.	Value.		Tons.	Value.
Pennsylvania.....		\$	Colorado.....		\$
Anthracite.....	32,265,421	72,274,544	Wyoming.....	1,210,769	3,051,590

Michigan.....	45,178	75,000	Totals.....	95,832,705	152,915,268
Alabama.....	2,225,000	2,990,000			
Georgia.....	133,929	180,000			

The amount consumed for local and colliery use would increase the total five or six per cent. Including all the coal thus consumed, the figures for the four years ending 1885 stand as follows, the value at the mine being added for each year, except that for 1885 the value of the "commercial coal" only is given:—1882, 92,219,454 tons, \$146,632,581; 1883, 102,867,969 tons, \$159,494,855; 1884, 106,906,295 tons, \$143,768,578; 1885, 99,069,216 tons, \$152,915,268.

The Appalachian coal-field does not occupy any portion of the State of New York, but extends from near its southern boundary south-west into Georgia and Alabama:—Pennsylvania, 12,302 square miles; Maryland, 550; Ohio, 10,000; West Virginia, 16,000; Virginia, 1000; Kentucky, 8983; Tennessee, 5100; Georgia, 170; Alabama, 5530; total, 59,635 square miles.

Pennsylvania, to which State the anthracite of the country is practically limited, produces more than half the coal raised in the United States, and about one-eighth of the total yield of the world, the increase during the past five years having been astonishingly rapid. Ohio stands next in importance among the States so situated as to have a portion of this field within their borders,—its yield, however, being only one-eighth of that of Pennsylvania. Maryland produces about one-third as much as Ohio. The production of the remaining States over which the Appalachian field extends is small as compared with the extent of their areas underlain by coal. In Kentucky and Alabama, however, some progress has been made within the past few years. About three-quarters of the coal mined in the United States is from the Appalachian field. Next in importance to the Appalachian is the Central coal-field, from which Illinois draws its supplies of fuel. The yield of that State is somewhat less than a fifth of that of Pennsylvania, while Indiana produces about one-fifth as much as Illinois. The coal of the Central field is decidedly inferior to that of the Appalachian, since it contains on the average considerably more ash and more water. The quality of the coal of the Western field is somewhat variable, but on the whole inferior to that of the Illinois field. The region over which it is spread is, however, not well supplied with forests; and hence the amount annually raised is considerable (nearly 4,000,000 tons for Iowa and 2,500,000 for Missouri). The southern extension of this field through Arkansas and Texas has, as yet, been very little explored or developed. The coal-producing areas of the Cordilleran region are all of comparatively small size, and no one of them is capable of furnishing a large supply for any considerable number of years; but taken together they are of great value, not only for local consumption, but for supplying the Mexican plateau. The Cordilleran coal (some call it lignite) is all newer than the Carboniferous; and it is not known that there is any coal at all, either in the Rocky Mountains or farther west, in that portion of the geological series which is the palæontological equivalent of the true "Carboniferous." A large part of the Cordilleran coal has a geological position close upon the line between the Cretaceous and Tertiary. By some palæontologists it is referred to the one, by some to the other. The quality of this newer coal is very variable: in some localities it is quite good, but in general it is decidedly inferior to the average coal of true Carboniferous age; some portions are distinctly lignitic in character.

While the amount of coal in the United States is large, it is not by any means so much larger than that of England as it has been always inferred to be from the simple consideration of the comparative dimensions of the areas over which coal is known to exist in the two countries. In the Central and Western fields the number of beds is small, and they are never of great thickness; nor is it known how far the total area embraced within the limits usually assigned as that of these fields was really originally underlain continuously by coal-seams, or how much of these seams has been removed by erosion. It is only in regard to the anthracite fields that even an approximate statement of the total remaining available quantity of coal can be made. Mr P. W. Sheaffer, a mining

engineer of long experience in that region, has made a statement that the anthracite fields originally contained about 25,000,000,000 tons of coal. Mr Ashburner, the assistant in charge of the State survey of the anthracite coal district, has stated that, up to 1st January 1883, the total production of that district had amounted to 509,333,695 tons. He also estimates that two-thirds of the coal actually attacked had been lost in the mining. Making allowance for increased consumption and other considerations, it would appear that 200 years must be taken as the maximum time during which the anthracite fields will hold out, while it is probable that they will be practically exhausted considerably earlier. As regards the quantity of available coal in any portion of the bituminous coal-fields of the country, the only estimate we have is that of Prof. Lesley, who (February 1886) estimates the amount of available coal in the Pittsburgh seam at 5,000,000,000 tons, but confesses that any exact calculation is impossible. If the consumption remains at the figure at which it stood in 1884 (11,000,000 tons), this quantity will last about 450 years.

Petro-
leum.

Petroleum.—The oil-producing districts of present or past importance are nearly all in Pennsylvania; but there are small productive areas in the adjacent portions of New York. (1) The Allegheny district, including the Richburg and several small outlying pools in Allegheny county, New York, has a productive area of 31 square miles, and up to January 1885 produced 15,000,000 barrels. (2) The Bradford district, embracing the oil-pools in central and northern McKean county, Pa., and southern Cattaraugus county, N.Y., has a productive area of 133 square miles, 121 of which are included in the Bradford field proper. The geological position of the oil-bearing strata is indicated by the fact that the uppermost oil-sand is, at Bradford, 1775 feet below the bottom of the lower member of the millstone grit, or Pottsville conglomerate, which in western Pennsylvania is one of the most persistent and best-recognized geological horizons, and is there known as the Olean conglomerate. This district had up to January 1885 produced 109,000,000 barrels of oil. (3) The Warren district lies in eastern Warren and north-eastern Forest counties, Pa.; it has an area of 35 square miles, and up to January 1885 had produced 12,000,000 barrels. The oils from different subdivisions of this district vary considerably in colour and gravity, although generally spoken of as "amber oils." They come from "sands" (sand rocks) of varying geological horizons, from 1100 to 1850 feet below the Olean conglomerate. (4) The Venango district—the scene of all the earlier oil developments—has an area of 65 square miles, and includes forty distinct and well-recognized oil-pools, the largest of which lies between Oil City on the south and Pleasantville on the north, and covers an area of 28 square miles. The production of this district up to January 1885 had been about 55,000,000 barrels. The oil of the Venango district comes from three principal sand beds, of which the uppermost one lies about 450 feet below the base of the Olean conglomerate. They are all contained within an interval of 350 feet. The oils are generally green, but frequently black, and sometimes amber. The pebbles of the sand rocks are water-worn, sometimes as large as hazel-nuts, loosely cemented together and bedded in fine sand; but the sands are not so regular or homogeneous as in the Bradford and Allegheny fields; consequently, the risk of obtaining unproductive holes and variable wells has always been greater in the Venango than in the Bradford and Allegheny districts. (5) The Butler district includes the oil-pools in Butler and Clarion counties and in south-eastern Venango county. The area is 84 square miles, and up to January 1885 the production had been about 69,000,000 barrels. The oil here comes from the same group of sand rocks as in the Venango district. (6) The Beaver district includes the two principal oil-pools known as Slippery Rock and Smith's Ferry, having an area of about 16 square miles, with a production of 1,000,000 barrels up to January 1885. In both the oil-pools of the Beaver district heavy oil is obtained from the representative of the Pottsville conglomerate, and amber oil from the Berea grit, a member of the Sub-Carboniferous series. The geological position of all the other oil-fields is considered by the geologists of the Pennsylvania Survey as Devonian. The total area of the productive oil areas is given by Messrs Carl and Ashburner at 369 square miles, and the general boundaries of the oil-regions of Pennsylvania are now regarded as established. That production is declining is shown by the following figures. In July 1883 the number of producing wells was 17,100, and the average daily product per well was 3.8 barrels; in 1884 the corresponding figures were 21,844 and 3.0, and in 1885 they were 22,524 and 2.5. Since July 1882, when the maximum average daily production for any one month was realized (105,102 barrels), there has been an irregular but steady decline. In 1884 the shipments of petroleum were more than 1,000,000 barrels in excess of the production. At the end of August 1884 the stock of oil on hand had reached its maximum, 39,084,561 barrels; in September 1885 it had declined to 35,343,771 barrels. The price of petroleum had

not, up to July 1885, been influenced by this condition of things, crude oil being at that time worth 92½ cents a barrel, 13½ cents less than the average price for 1884. The extraordinary fluctuations in the price of petroleum during 1880 to 1886 are shown by the following figures:—in 1880 it ranged from 124½ to 70½ cents per barrel for crude oil; in 1881 from 100½ to 72; in 1882 from 135 to 49½; in 1883 from 125 to 84½; in 1884 from 115½ to 51; in 1885 from 111½ to 68; in 1886 from 92½ to 59½. These figures, however, have but little reference to changed conditions of production. The fluctuations are simply the result of a colossal system of gambling, the magnitude of which may be inferred from the statement that the "clearances" on the "consolidated stock and petroleum exchange" for 1886 amounted to about 2,275,000,000 barrels. The daily average exports of petroleum for that year are given at about 44,300 barrels. The tendency to lower prices in 1886 was due in part to the remarkable yield of the oil-wells at Baku, on the Caspian Sea, and in part to discoveries, supposed to be of importance, in Ohio.

Natural Gas.—The use of natural gas for illumination, and even Natural for metallurgical purposes, has lately become a matter of importance. The existence of outflows or springs of gas in the region west of the Allegheny range has been long known, and the gas obtained from wells or bore-holes was used for illumination in Fredonia, N.Y., as early as 1821. One well after another was bored for this purpose at that place, until, in 1880, the supply had reached the amount of 110,000 cubic feet per month. The following figures, reported by T. P. Roberts, show the estimated value of the coal displaced by natural gas in the region where this source of heat and light was in use for the years mentioned:—

1882. Pittsburgh region,	\$75,000;	elsewhere,	\$140,000;	total,	\$215,000
1883. " "	200,000;	"	275,000;	"	475,000
1884. " "	1,100,000;	"	360,000;	"	1,460,000

Gas seems to be a general concomitant of the oil all through the petroleum region, but for a long time the outflow of gas from the oil-wells was looked upon as a nuisance. According to Mr Ashburner,² the amount of gas at present flowing from the explored sands of Pennsylvania is probably two or three times greater than is required to meet all present demands. The same authority gives an account of the development of the natural gas resources of Ohio. Their amount is not yet ascertained with any degree of certainty, but it seems likely to be large. All the gas comes from the Palæozoic strata, from the Upper Coal-measures down to the Trenton limestone,—the most prolific gas-bearing rocks being the Berea grit in the Sub-Carboniferous and the Trenton limestone of Lower Silurian age. Natural gas has been obtained in numerous localities in New York, but nowhere in considerable quantity except in the vicinity of the Allegheny oil-district, in the county of that name. Portions of West Virginia, especially the Kanawha valley, give promise of being regions of large production.

Iron and Steel.—The following table (VII.) will convey an idea of the condition of the iron industry at the date of the last census, and of the progress made during the ten preceding years:—

	No. of Establishments.	Amount of Capital Invested.	Value of Products.	Weight of Products in Tons.
1870	808	\$121,772,074	\$207,208,696	3,245,720
1880	1005	290,971,884	296,557,685	6,436,730
Increase per cent.....	24.38	89.68	43.12	98.76

The "weight of products," as given above, includes the products of all the various processes or operations; hence there is evidently a certain amount of duplication (rolled iron, for instance, being mainly produced from pig). The following table (VIII.) gives the production in each branch of the steel and iron industries:—

	1870.	1880.
Pig iron and castings from furnace	1,892,876 tons.	3,875,901 tons.
All products of iron rolling mills	1,287,347 "	2,101,114 "
Bessemer steel finished products	17,324 "	794,550 "
Open-hearth steel finished products.....	0 "	83,163 "
Crucible steel finished products	25,061 "	62,784 "
Blister and other steel	2,040 "	4,424 "
Products of forges and bloomeries	98,935 "	64,784 "

The distribution of the iron industry is extremely irregular. West of the Mississippi, with the exception of the angle between that river and the Missouri adjacent to St Louis, the amount of iron made is very small. The percentage of total production in 1880 was distributed as follows:—Pennsylvania, 50; Ohio, 13; New York, 8; Illinois, 6; New Jersey, 3; Wisconsin, W. Virginia, Michigan, and Massachusetts, each nearly 2; Missouri, Kentucky, and Maryland, between 1.5 and 2; Indiana and Tennessee, about 1; all the other States and Territories, an aggregate of about 4 per cent. New England now makes but little pig iron, and the South scarcely any rolled iron; the West has largely embarked in the manufacture of steel by the Bessemer process, while New York has not a single Bessemer establishment; New York manufactures chiefly

¹ The substance of the following paragraph is mainly derived from a paper read by Mr C. A. Ashburner, of the Pennsylvania Geological Survey, at a meeting of the American Institute of Mining Engineers in September 1885.

² Paper read before the American Institute of Mining Engineers, Oct. 1886.

from ore, and Pennsylvania from pig and scrap iron; Michigan is the leading producer of charcoal pig iron, and now makes no other kind; only five States make Bessemer steel; and two States, Pennsylvania and New Jersey, produce nearly all the crucible steel.

The census year 1880 was one of exceptional prosperity for the iron and steel industries of the country. The production of pig iron and of Bessemer steel ingots and rails since 1880 is shown in the following table (IX.), from the statistics collected by the American Iron and Steel Association:—

	1881.	1882.	1883.	1884.	1885.	1886.
Pig iron	4,144,258	4,623,323	4,595,510	4,097,868	4,044,526	5,683,329
Bessemer steel ingots.....	1,374,247	1,514,687	1,477,345	1,375,317	1,519,426	2,269,190
Bessemer steel rails.....	1,187,769	1,284,066	1,148,709	996,465	959,470	1,562,409

The total number of completed Bessemer steel works at the close of 1886 was 33, with 69 converters. Pennsylvania in that year made 59 per cent. of the ingots produced, Illinois 21, and other States 20. In the following table (X.) the amount of steel of all kinds produced is given (in tons) for the years stated:—

	Bessemer Steel Ingots.	Open-Hearth Steel Ingots.	Crucible Steel Ingots.	All other Steel.	Total.
1870	37,500	1,339		31,250	70,089
1875	335,283	8,080	35,179	11,256	389,799
1880	1,074,261	100,850	64,664	7,558	1,247,334
1885	1,519,430	133,375	57,599	1,514	1,711,919
1886	2,269,190	218,973	71,972	2,366	2,562,502

By far the largest production of iron ore in the United States is from the rocks which lie below the Lower Silurian—the Azoic series of Foster and Whitney and the Archæan of Dana. In this formation the ore occurs in immense quantity—in what may without exaggeration be called mountain masses, which in many cases exhibit all the evidences of an eruptive origin, as in the case of the Iron Mountain of Missouri, or in some of the localities in the Marquette and Menominee regions of Lake Superior. At the first-mentioned locality the ore is intimately associated with an undoubted eruptive rock, with which it is intermingled in such a manner as to show that the two—ore and rock—must have had one and the same origin. A similar condition of things is revealed on Lake Superior, where the ore occurs in repeated interlamination between sheets of unquestionably eruptive material. The ores thus occurring are hæmatite or specular ore and magnetite, with some hydrated oxide, or limonite, the result of the action of water on the previously formed hæmatite. They are in general extraordinarily free from deleterious ingredients, especially phosphorus and sulphur, although usually containing a small amount of silica. The purity of these ores is a strong indication of their origin differing from that of ordinary sedimentary deposits. Many of the analyses of Lake Superior ore show the presence of only a few hundredths of one per cent. of phosphorus. The most important district in which these ores occur is the south shore of Lake Superior, and the most important port of shipment is Marquette, a considerable amount being also shipped from Escanaba on Lake Michigan. From 1856 to 1886 the total shipments of iron ore from the region amounted to 31,030,160 tons. A district known as the Vermilion Lake iron district, in which the ore has similar characters, and where the quantity is believed to be very large, has been recently opened in Minnesota, on the north shore of Lake Superior. The Iron Mountain region, a little less than a hundred miles south of Saint Louis, although small, is of considerable importance. A very large portion of the Lake Superior ores goes to the Appalachian coal-field to be smelted; and this was formerly the case with the Iron Mountain ore, but the latter is now used in nearer localities. There is a very important and apparently inexhaustible deposit in Lebanon county, Pennsylvania; the ore is chiefly magnetite, and its mode of occurrence in close connexion with an eruptive rock is to the present writer strong, if not absolutely convincing, evidence of its igneous origin. There are important deposits of iron ore, on the eastern border of New York, especially in the Adirondacks, and along the Hudson River. The geological position in which a portion of these ores occurs is certainly the same as that of the ores of Lake Superior—namely, the Azoic. That is the character of the Adirondack ores, which have long been and still are extensively worked. The localities are chiefly in Clinton, Essex, and Franklin counties. In the last-named county are the very extensive Chateaugay mines. The ores of this region are chiefly magnetite, but they often contain too much phosphorus to be used in the manufacture of steel. There are important occurrences of magnetic ore near New York city and also near the Hudson river, in Orange, Rockland, Putnam, and Columbia counties. Some of these ores are adapted to the manufacture of Bessemer steel. The mode of occurrence of the ores in southern New York and northern New Jersey is peculiar; they are not so distinctly eruptive as are the ores of Missouri and Lake Superior. One authority regards the New Jersey ores as unquestionably of sedimentary origin. This New Jersey

district is not in a flourishing condition at present, since the ores, as a rule, are not adapted to the manufacture of Bessemer steel. Similar ores occur at many points, and often in large quantity, in the Azoic or crystalline belt of the Appalachian system, in the States lying farther south than New Jersey. In Mitchell county, North Carolina, is a deposit known as the Cranberry Bank, of which the quality is excellent, and the quantity is believed to be very great. Up to the present time, however, but little of this ore has been shipped. Next to the Azoic ores in importance, but decidedly inferior in quality, are those of the Clinton group, a member of the Upper Silurian series. The ore occurring in this geological position is known by various names, the most common ones being fossil or dyestone ore. It is a red hæmatite, not crystalline like the specular variety of the peroxide, but usually in a more or less granular or concretionary form, that of flattened grains resembling flax seed being a common mode of occurrence, whence the name "flax-seed ore." This deposit occurs at many points along the outcrop of the Clinton group all the way around from Wisconsin, through Canada and New York, into Pennsylvania, and down the eastern slope of the Appalachian range to Georgia, and is said to be the most extensive deposit of iron ore in the world yet discovered. The fossil ore, though large in quantity, contains too much phosphorus to be used for making steel in the ordinary method; but, being in places favourably situated with regard to fuel, and yielding as it does a satisfactory quality of cast iron, it is quite extensively mined at various points. Next to the Clinton ore in importance comes the brown hæmatite ore (limonite), which occurs in numerous localities, but of which the most extensive deposits are those occurring in the Lower Silurian limestones of the Appalachian system, and especially along the line of the Great Valley. Some of the ores are of excellent quality, notably those of Litchfield county, Connecticut, in the so-called Salisbury district. The iron made in charcoal furnaces in this region is considered as being of the highest value for articles in which strength and toughness are essential. Carbonate of iron, in the form of spathic iron, is of rare occurrence. The argillaceous carbonates (clay ironstone) are also of comparatively little importance, although used to some extent, especially as mixed with other ores, in western Pennsylvania and Ohio. The coal-fields west of the Appalachians are very poorly supplied with iron ores. Black-band ore is also of somewhat rare and limited occurrence in the United States.

In spite of the abundance of iron ore in the United States and the existence of a heavy protective duty (75 cents per ton), a large quantity of ore is imported from abroad—chiefly from Spain, Elba, Algiers, and Cuba (1,039,433 tons valued at \$1,912,437 in 1886). Almost all this was used in Pennsylvania, and chiefly in the manufacture of Bessemer pig iron and spiegeleisen. Up to 1884, at least, no pig iron suitable for the manufacture of Bessemer steel by any process now in use in the United States had ever been made south of the Potomac or south of Wheeling. Neither has iron suitable for crucible steel been made in the United States which can compete with that of Sweden.

The annexed table (XI.), published by Mr Swank, shows the production of iron ore in tons in the leading ore-producing districts for the years 1884, 1885, and 1886:—

	1884.	1885.	1886.
Lake Superior (Michigan and Wisconsin).....	2,455,924	2,281,004	3,258,174

Gold and Silver.—The washing of the high or Tertiary gravels Gold and by the hydraulic process and the working of mines in the solid rock silver. did not, on the whole, compensate for the diminished yield of the ordinary placer and river diggings, so that the produce of gold in California continued to fall off, and by 1860 had decreased to about half what it had been ten years before. Discoveries in other Cordilleran Territories, notably in Montana and Idaho, made up, however, in part for the deficiency of California, so that in 1860 the total amount of gold produced in the United States was estimated at not less than \$45,000,000. In the latter part of the decade 1850-59 the Territories adjacent to California on the east, north, and south were overrun by thousands of miners from the Sierra Nevada gold-fields, and within a few years an extraordinary number of discoveries were made, some of which proved to be of great

importance. The most powerful impulse to mining operations, and the immediate cause of a somewhat lengthy period of wild excitement and speculation was the discovery and successful opening of the Comstock lode in 1859, in the western part of what is now the State of Nevada, but was then part of the Territory of Utah, and known as the "Washoe Country" (from a small tribe of Indians of that name). The locality of the lode, where there soon grew up a large town called Virginia City, is about 20 miles east of the boundary of California, and nearly due east of the northern end of Lake Tahoe. As early as August 1860 two mills were at work stamping and amalgamating the ore from the lode; mining had begun on a large scale; and many ingenious metallurgists were endeavouring to ascertain experimentally how the somewhat complex metalliferous combinations there occurring could be best and most economically treated. So far as quantity of bullion produced is concerned, these operations were eminently successful. The various estimates of the total yield of the lode from the time of its discovery to 30th June 1880, collected and published by Mr Eliot Lord, run from \$304,752,171.54 to \$306,181,251.05. The total production to the end of 1886 may be estimated as having been not far from \$320,000,000. The bullion obtained from the milling of the ores contains about an equal amount in value of silver and gold. The mines on this lode thus added to the bullion stock of the world \$100,000,000 more in eighteen years than the whole Freiberg district in Saxony had furnished in a little over 700 years (1168-1875). The lode is an ore channel of great dimensions, included within volcanic rocks of Tertiary age, which themselves have broken through pre-existing strata of Triassic age. It exhibits some of the features of a fissure vein, combined with those of a contact deposit in part and of a segregated vein in part. The gangue is quartz, very irregularly distributed in bodies often of great size, and for the most part nearly or quite barren of ore. The metalliferous portions of the lode, "bonanzas," as they are here generally called, are usually of great size, but extremely irregular in their position. Their number has been about twenty, most of them lying near the surface; but the last important one discovered was struck at a little over 1000 feet below the surface. Its dimensions were—according to Mr Church—about 700 feet in length, by 500 deep, and 90 wide; the average yield \$93.55 per ton; and the total value of the bullion obtained from it \$104,007,653. The mines on this lode have been worked to a greater depth than any mines in the world extending over an equal amount of ground. Up to October 1886 work was still being carried on at several points below the depth of 3000 feet. The lower levels, below that of the Suto tunnel, which intersects the lode at a point about 2000 feet below its outcrop, are now abandoned. Workings are still going on, however, above the great adit level, where there yet remain considerable bodies of low grade ore, which can perhaps be extracted with moderate profit, since more economical methods have been introduced both in mining and milling. The yield of the Comstock lode at present, although small as compared with that of its prosperous years, is still much larger than that of all the mines in the Freiberg district of Saxony.

The success of the Comstock lode workings led to the active exploration of the whole adjacent region, with the result that a great number of localities were discovered where auriferous and argentiferous ores occur, and some of these have been extensively wrought and have produced largely. In very few, however, do the ore deposits bear the distinguishing characters of true or fissure veins. Special mention may be made of the Meadow Valley and Raymond and Ely mines in Lincoln county. The first-named mine is in Pioche, 273 miles south of Palisade station on the Central Pacific Railroad; the enclosing rock is quartzite of Lower Silurian age, the veins varying in width, but averaging from 2 to 2½ feet, the ore being carbonate of lead near the surface with chloride of silver, passing into sulphurets, as usual, in going down. At the end of 1873 this mine was 1100 feet deep, and a large body of ore had been struck yielding \$300 in value of silver per ton. The culminating years of the prosperity of these mines were 1872 and 1873, and the yield of the Ely district for those years respectively was \$5,321,007 and \$3,735,596. The Eureka district in the central part of Nevada is of importance on account of the magnitude of its yield, and because mining and smelting operations have been carried on uninterruptedly since 1869, thus affording great facilities for scientific investigations. Its ores are chiefly galena, accompanied by the various oxidized combinations resulting from its decomposition. Similar ores of zinc are also present, but in much smaller quantity. These ores are rich in gold and silver (average—15 per cent. lead, 0.079 silver, and 0.00248 gold). The rocks in which they occur are chiefly limestones, and of Lower Silurian age; the deposits are very irregular in form. In many of their features they closely resemble the so-called pipe-veins of the North of England lead mines. Much of the ore has become decomposed, and has been subjected, since decomposition, to a rearrangement by water, analogous to stratification. The total yield of the Eureka district from 1869 to 1883 is stated at about \$60,000,000 in value of gold and silver, and about 225,000 tons of lead. According to present indications, this district is approaching exhaustion.

Utah has important mines resembling to a considerable extent those at Eureka. The Hornsilver mine at Frisco, in southern Utah, is a large contact deposit, 30 to 50 feet wide, between dolomitic limestone and an eruptive rock called rhyolite or trachyte. The ores are sulphate of lead with some carbonate, associated with heavy spar, which occurs chiefly near the wall of eruptive rock. This mine has paid \$4,000,000 in dividends, but none since 1884. The Little Cottonwood district, at a height of over 10,000 feet in the Wahsatch range, shows a record of about 3500 "locations" made within an area 2½ miles square. It includes the famous Emma mine, where a large body of ore occurred occupying an egg-shaped cavity in the Carboniferous limestone, which yielded largely (over \$2,500,000); but it was soon worked out. The Flagstaff mine in the same cañon, a "pipe-vein" or deposit occupying several irregular cave-like openings in the limestone, seems also to have been nearly or quite worked out. One of the largest and most productive mines in the country, and the most important one in Utah, is the Ontario, in the Uintah district, Summit county. The vein seems to be, in the lower levels at least, a contact mass between walls of quartzite and highly decomposed eruptive rock (called porphyry), and it varies in width from a few inches to 15 feet. It was discovered in 1872, has been worked by a company with \$15,000,000 capital since 1877, and up to February 1887 had paid \$8,075,000 in dividends. The Silver Reef district in Washington county is a region of remarkable interest, where sandstones of Triassic age have been broken through and invaded by eruptive masses (andesites and trachytes), and where the ore, according to Prof. Reyer, occurs in flat masses and impregnations between the strata, adjacent to the eruptive rock, and is especially largely developed in contact with the remains of plants with which the rock is filled. The ores are carbonate of copper with chloride of silver, passing into the sulphuret at depths. According to the same authority, these mines produced a few years ago over a million of dollars a year; but they have much fallen off of late. The census report of 1880 gives the total product of the district up to 1st June 1880 at a little over \$3,250,000.

The metalliferous deposits of Colorado are important from their magnitude and variety.¹ Of the actual precious metal production, by far the largest portion is derived from pyrites and galena and their decomposition products. The telluride ores of Boulder county and the auriferous pyrites of Gilpin county, with a few individual deposits in the southern portion of the State, constitute the source from which it is derived. With these exceptions its mineral deposits may be considered as essentially silver-bearing. The principal source of silver is argentiferous galena and its decomposition products, while argentiferous grey copper or freibergite is, next to this, the most important silver-bearing mineral. The sulphides of silver also occur, and in some cases bismuth is found in sufficient quantity to constitute an ore. As yet, so far as known, no copper is extracted except as an adjunct in the reduction of silver-bearing copper ores. Placer deposits are generally confined to the valley bottoms among high mountain ridges; their present yield is relatively inconsiderable. Before the silver ores of Leadville were discovered, mining in Colorado was principally confined to approximately vertical veins in the Archean rocks of the Front range or in the eruptive rocks of the San Juan region; but since the limestone deposits of the Mosquito range have proved so exceptionally rich attention has been more and more turned to the ores in sedimentary rocks, and many new districts have been discovered, but none to rival that of Leadville. The Leadville ores are flat sheets, of the kind often designated in the Cordilleran mining regions as "blanket deposits," and appear to be contact deposits between the Carboniferous limestone and the overlying felsite, with additional or incidental ore accumulations in the limestone in irregular cavities. According to reports locally published the product of the Leadville "smelters" or smelting works in 1886 was—lead, 51,925,546 lb; silver, 4,569,013 oz.; gold, 22,504 oz.; total value, \$7,515,148. From the mode of occurrence of the Leadville deposits it seems probable that they will within a few years become practically exhausted. The area over which the blue limestone of Emmons (dolomite of Rolker) has been found in places productive is, however, very large, having been estimated at 225,000,000 square feet. The Montana deposits, which up to 1880 are reported to have yielded fully \$50,000,000, seem now to have been pretty much worked out. The workings from which the ores are now chiefly obtained appear to be of the class of segregated veins. The ores consist largely of auriferous pyrites in a gangue of quartz, oxidized in their upper portions and there easily manipulated, but in depth passing into the more refractory sulphurets. Unlike the ores described as occurring in Colorado and Utah, they are accompanied by copper rather than by lead, and they are also rather manganiiferous than ferriiferous. Much yet remains to be done before their nature and value can be fully understood; and the same may be said of the adjacent Territory of Idaho, the auriferous gravels of which resemble those of Montana, and have been next to those of California and Montana in import-

¹ See Census Report for 1880 (1885).

ance (total yield to date estimated at \$30,000,000). The deep gravels of Boisé basin seem to be exceptional, and to resemble the deep or high gravels of California. A very large portion of the mines (other than placer) of Idaho appear to be of the fissure class, and to be enclosed in a country rock of granite, resembling in many respects the veins of the vicinity of Austin in Nevada. In Arizona, which ranks along with Idaho in the production of the precious metals, and is next to Michigan and Montana as a producer of copper, the mode of occurrence of the metalliferous deposits is complicated and varied, and is still very imperfectly known. They appear to be largely of the nature of contact deposits, dependent on the presence of some ancient or modern eruptive mass. The famous Tombstone district, in Pima county, has been a productive one, but seems at present to be declining.

TABLE XII.—*Gold and Silver Production of the Different States and Territories for 1885 (in Thousands of Dollars).*

	Gold.	Silver.	Total.		Gold.	Silver.	Total.
Alaska.....	300	2	302	North Carolina.....	152	3	155
Arizona.....	880	3,800	4,680	Oregon.....	800	10	810
California.....	12,700	2,500	15,200	South Carolina.....	43	...	43
Colorado.....	4,200	18,800	20,000	Utah.....	180	6,750	6,930
Dakota.....	3,200	100	3,300	Washington.....	120	70	190
Georgia.....	135	...	135	Other States and Territories.....	90	5	95
Idaho.....	1,800	3,800	5,600	Total.....	31,801	51,600	83,401
Montana.....	3,300	10,080	13,380				
Nevada.....	3,100	0,000	3,100				
New Mexico.....	800	2,000	2,800				

The production of gold in the United States for each of the seven years 1880-86 inclusive is estimated (in millions of dollars) as—36, 34.7, 32.5, 30, 30.8, 31.8, 35. Similarly the coining value of the silver produced during the same years is returned as—39.2, 43, 46.8, 46.2, 48.8, 51.6, 51. The commercial value of silver has, however, of late been considerably less than the coining value—42, 42.5, and 39.4 in 1884-85-86.

Mercury. All the quicksilver produced in the United States comes from California, although small quantities of the ores of this metal have been obtained at various points in Colorado, and also in New Mexico. A little mercury has also been produced in Oregon. The Californian mines are all in the Coast ranges, in rocks of Cretaceous age. Small veins of quartz containing a little cinnabar have been found in the Sierra Nevada; but this ore is not known to exist anywhere in that range in workable quantity. The mercurial ores of the Coast ranges occur in very irregular deposits, in the form of strings and bunches, disseminated through a highly metamorphosed silicious rock. The first locality where this metal was successfully mined was New Almaden, about 100 miles south of San Francisco. Another locality—New Idria—about 100 miles still farther south, has also been productive, but in a less degree. Mercury ores have also been mined at several points north of San Francisco, in the neighbourhood of Clear Lake, where they occur, not only in metamorphic Cretaceous strata resembling those of New Almaden, but also in recent volcanic rocks, where gold has sometimes been found in intimate association with the cinnabar. The New Almaden mine has been productive since 1850, but the yield has varied greatly from year to year, partly on account of the irregularity of the mode of occurrence, and partly on account of interference on the part of the United States based on a question of title to the property. The most productive year was 1876, when the number of flasks (of 76½ lb) obtained was 47,194. The number produced in 1880 was 23,465, and in 1886 18,000. The total produce of the Californian mines was 59,926 flasks in 1880, 60,851 in 1881, 52,732 in 1882, 46,725 in 1883, 31,913 in 1884, 32,073 in 1885, and 29,981 in 1886. No new discoveries of localities of importance have been made during the past few years, and the mines now worked in California are all in a depressed condition.

Tin. Tin has been discovered in numerous localities, and various attempts have been made to open mines—in Maine, New Hampshire, Virginia, Alabama—but hitherto the amount of the metal produced has been quite insignificant. The region from which most has been expected is the Black Hills of Dakota, about 20 miles south-west of Rapid City. The occurrence of the tin ore and the associated minerals at the mine to which the name of Etta has been given is very similar to that of the ores in the Erzgebirge. The cassiterite is disseminated through a granitic or granitoid rock in irregular bunches, strings, and even masses, associated with the usual minerals. There has not hitherto been any production of commercial importance from this source.

Copper. The present sources of copper are almost exclusively the Lake Superior region, and the Territories of Montana and Arizona. The mines of Lake Superior are the only important mines in the world in which the metal is exclusively obtained in the native state. The mode of occurrence of the copper varies, however, considerably in different portions of the mining district, which extends from Point Keweenaw along the southern shore of the lake to a little beyond the Ontonagon river. The most productive mines at present are those in the vicinity of Portage Lake, about half-way

between the eastern and western extremities of the cupriferous range. The rock in which the metal occurs is an old basalt, much metamorphosed from its original condition, and in the form now generally called melaphyre. This belt, commonly known in the region as the "trap range," is a volcanic material, interbedded in numerous alternating layers with sandstone and conglomerate, equivalent geologically to the Potsdam sandstone of the New York Survey or the Primordial of Barrande. The metal occurs along nearly the whole extent of Keweenaw Point in veins crossing the formation, and having all the characters of true fissure veins, the gangue being a mixture of quartz and calcite with various zeolitic minerals. Copper in large masses has been found in various mines on Lake Superior, but in none of such great dimensions as at the Minnesota mine, near the Ontonagon river. The largest mass discovered here weighed about 500 tons. Its length was 46 feet, its breadth 18½, and its maximum thickness 8½. While a considerable amount of copper has been obtained on Lake Superior in large masses, and lumps too small to be shipped separately, and therefore put in barrels and called "barrel-work," much the larger portion occurs in small grains, scales, and strings, disseminated through the rock. For crushing rock of this character a new form of stamp known as the Ball stamp was invented, one head of which is capable of crushing from 220 to 250 tons of rock in twenty-four hours. The most interesting mine on Lake Superior, and indeed the largest and most important—not being an open-work—in the world, is that of the Calumet and Hecla Company. The mode of occurrence of the copper, which is all in the metallic form, and like that of the other Lake Superior mines almost chemically pure, is peculiar. The cupriferous mass is a bed of eruptive material, interstratified with other masses of similar origin, but itself a conglomerate made up chiefly of more or less rounded pebbles of eruptive rock—rhyolite, trachyte, and basalt—cemented together by native copper. The Calumet and Hecla mines, which form one connected work, have been opened over a length of about 1½ miles, and to a depth, on the inclination of the metalliferous bed, which is about 39°, of about 3800 feet. The number of men employed is about 2800, and the production for 1886 was 22,552 tons (the total amount since 1866 being 201,529 tons).

The copper mines of Montana are chiefly in the vicinity of Butte City. The really important operations seem to be pretty closely limited to an area only 2½ miles long by 1 mile wide, within which are three important silver mines, as well as the copper mines which make the district so famous. There are two great classes of mineral occurrences,—cupriferous veins, carrying more or less silver, and silver veins, with a manganese gangue, which carry little or no copper. These two groups have certain features in common. They all occur in granite, and are all accompanied by zones of decomposed country rock, which run parallel to and usually form the walls of all the large copper veins that have been opened to any great depths, and which are called porphyry dikes by the miners, but are really granite altered by the chemical changes which have accompanied the formation of the lode. They all pitch vertically or nearly so, and lack entirely the well-defined walls and the selvages which are characteristic of fissure veins. The cupriferous veins appear on the surface as wide bands of quartzose rock, much decomposed and stained with gossan. The surface ore always carries silver, is almost entirely in a free-milling condition, and generally in paying quantity. Nearly all the lodes at present worked for copper were at first worked for silver, and this condition continued until the water-line was reached, when the base ores—mainly the ordinary sulphuretted combinations of copper and of copper and iron, especially copper glance or vitreous copper and erubescite or variegated, peacock, and horseflesh ore—set in. The veins are of great size, being often thirty feet wide for several hundred feet in length. The average width of pay ore in the copper veins is stated to be not less than 7 feet; the Anaconda—the widest of any yet opened—averages over 12 feet of profitable ore, and in many places widens to 30 or 40 feet for a great distance, showing no diminution in richness at the depth of 800 feet. In a part of these veins—as, for instance, the Anaconda and Liquidation—the ore is copper glance in a gangue of quartz and decomposed feldspathic rock; while another type of veins, represented most perfectly by the Parrot vein, has nearly its entire metallic contents in the form of erubescite. This last-mentioned vein is also of great importance for its silver. The veins of the manganese-silver group lie all within a small area, but are of much interest and value. The gangue is quartz, heavily charged with its various oxidized combinations of manganese, all more or less argentiferous, the amount of silver ranging from three or four to several hundred ounces of that metal per ton. In these manganese veins the transition from decomposed oxidized combinations to the hard silicate and carbonate of that metal at the water-line is as sudden and striking as that from oxidized to sulphuretted ores in the previously-mentioned class of veins. An exceptional occurrence in this district is that of the Gagnon mine, of which the gangue is chiefly quartz, and the ore argentiferous zinc blende.

There has of late years been a falling off in the production of

copper in Arizona, but this appears to be due to unfavourable situation with reference to a market rather than to exhaustion. The Santa Rita mines, in New Mexico, near the Arizona line, were the first worked in that region, but are at present idle. The original workings were for metallic copper, occurring near the contact of a bed of limestone with an eruptive rock resembling felsite, the whole deposit being one of irregular character. Near the junction of the felsite and the limestone there is a series of parallel veins, in which the copper occurs in the form of carbonates and oxides. The Clifton district has been the scene of continuous mining operations since 1872, and is at present the largest producer of copper in the south-west. Its cupriferous deposits have been divided into three classes,—those occurring in limestone, those associated with porphyry, and those in the granite. The ores of the first class are the red oxide in a gangue of compact hematite and the carbonates in a gangue of brown manganese ore. The ores of the second and third class are oxides and oxysulphides, changing into copper glance at a trifling depth, and into yellow sulphurets in the deepest workings. The deposits are irregular, in some respects resembling contact deposits, and in others the metalliferous occurrences in the North of England lead mines. They are called by many mining geologists "pockets"; but other authorities consider them true veins. The most productive mine of the district—the Longfellow—is described as being an almost vertical fissure in stratified limestone, at or near its junction with a dike of felsite.

TABLE XIII.—Copper Production of United States (in Tons) from 1882 to 1886.

	1882.	1883.	1884.	1885.	1886.
Lake Superior	25,438	26,653	30,961	32,209	35,593
Montana	4,043	10,658	19,238	30,267	25,719
Arizona	8,029	11,010	11,935	10,137	6,989
Other localities	2,957	3,253	2,574	1,438	1,340
Total domestic copper	40,467	51,574	64,708	74,051	69,641
From imported ores ..	446	726	1,276	2,271	2,000
Total	40,913	52,300	65,984	76,322	71,641

Zinc.

Zinc has become within the past few years an important article of production. The ores are found in very numerous localities, usually in connexion with those of lead, both in the Appalachian range and throughout the comparatively undisturbed Palaeozoic regions of the Mississippi valley. The Illinois zinc furnaces are at Peru, La Salle, and Collinsville; those of Missouri mostly at Carondelet near St Louis, but there is one at Rich Hill and one at Joplin. Those of Kansas are at Pittsburg, with the exception of one at Weir City. There is also a small establishment at White River in Arkansas. There are also zinc works at Bergen Point, N.J., and at Bethlehem, Pa., and one small establishment in Tennessee.

TABLE XIV.—Total Zinc Production (in Tons) from 1881 to 1885.

	1881.	1882.	1883.	1884.	1885.
Illinois	14,509	16,250	15,037	15,708	17,345
Kansas	4,464	6,576	8,500	7,017	7,591
Missouri	2,455	2,232	5,116	4,670	4,175
Other States	5,087	4,770	7,018	7,216
Total	30,145	33,423	34,413	36,327

Lead.

The lead production was for many years, as already mentioned, limited to two districts near the Mississippi,—one, the so-called "Upper Mines," covering an area of 3000 to 4000 square miles included within the States of Wisconsin, Iowa, and Illinois; the other, the "Lower Mines," in south-eastern Missouri. The yield of the Upper Mines reached its culminating point about 1845; and in 1852 it had fallen off to about 15,000 tons. That of the Missouri mines also fell off, so far as the south-eastern district was concerned, but the loss was more than compensated by discoveries of ore in south-western Missouri, and later in the adjacent State of Kansas. The production of all these districts (the lead of which contains but a trace of silver) for the years 1880-1884 is given by Mr E. A. Caswell as follows:—24,700 tons in 1880, 27,470 in 1881, 25,900 in 1882, 19,300 in 1883, and 17,567 in 1884. A considerable portion of the recently renewed activity in the Missouri mines is due to the increased utilization of the zinc ores associated with the galena. The numerous lead mines opened and worked in various States in the Appalachian region, from Maine to North Carolina, have nearly all proved unsuccessful. Yet, on the whole, the country has largely increased its product—a result due, chiefly, to the discovery and successful working of various lead ores containing silver in sufficient quantity to pay for separation, in several of the Cordilleran States and Territories. The total yield was 87,340 tons in 1880, 104,540 in 1881, 118,650 in 1882, 128,515 in 1883, 124,908

in 1884, 115,546 in 1885, distributed in 1883-84 as follows (Table XV.) :—

	1883.	1884.		1883.	1884.
Utah	25,900	25,000	New Mexico	2,100	5,350
Nevada	5,350	3,570	Arizona	1,350	2,400
Colorado	63,000	56,400	California	1,500	1,420
Montana	4,500	6,250	Mississippi Valley ..	19,300	17,567
Idaho	5,350	6,700	Virginia	190	220

To the non-metallic mineral substances mined or quarried in the United States, apart from coal and petroleum, which have been already considered, only very brief reference can here be made. The value of the lime and building-stone used in the country in 1885 was, for each of these articles, at least as great as that of the petroleum. Coal alone constitutes nearly seven-tenths of the value of the non-metallic minerals mined, and coal, petroleum, building-stone, and lime together make up almost nineteen-twentieths of the same total. Other important articles are—salt (value \$4,825,345 in 1885), cement (\$3,492,500), phosphate-rock (\$2,846,064), and limestone for flux in iron manufacture (\$1,694,656).

The utilization of the brine springs of New York and Virginia Salt was begun towards the end of the last century, and has become extensively developed. To this development has been added that of similar saline resources in Ohio and Michigan. Previous to this, however, some salt had been made by the evaporation of sea-water at points along the coast, and especially in the neighbourhood of Massachusetts Bay; and the census of 1880 showed still six establishments of this kind in existence, producing nearly 10,000 bushels of salt per annum. In California the evaporation of sea-water has attained some importance (884,443 bushels in 1880), the climatic conditions being much more favourable than along the northern Atlantic. A very small amount of salt was also made on the Florida coast. There are various lakes and partially or wholly dried-up beds of former lakes in the Cordilleran region, which are capable of furnishing a large quantity of salt, and some of these have been worked to a limited extent for use in metallurgy. By far the larger portion of the salt manufactured in the United States comes from the evaporation of brine, obtained by boring. The produce of the four brine-producing States (in bushels of 56 lb) is given as follows in the census report for 1880 :—Michigan, 12,425,885; New York, 8,748,203; West Virginia, 3,105,333; Ohio, 2,650,301; total, 26,929,722; total production of all the States, 29,800,298. The New York salt region is in the centre of the State, near Syracuse. The brine is obtained in a detrital deposit, varying in size from the coarsest gravel to the finest sand, which fills depressions in the Onondaga or Salina shales, to the depth in places of 300 or 400 feet. These shales are of Upper Silurian age. No rock-salt has been struck by boring; but farther west, at various points in New York, Canada, and Michigan, the presence of large bodies of salt has been proved by the aid of the diamond drill. As yet, however, this source of supply has only been utilized to a limited extent. The salt of Michigan comes from several distinct geological horizons. The uppermost one is in the Coal-measures, the next lower in the Lower Carboniferous, and the lowest in the Onondaga or Salina salt group, the salt-bearing formation of New York. It is only in the last-named formation that rock-salt has been found in Michigan, namely, at Bay City, on Saginaw Bay, where, at a depth of 2085 feet, a bed of salt 115 feet in thickness was bored through. In the Saginaw valley salt can be produced more cheaply than anywhere else in the country; the business of salt-making is associated with that of sawing lumber, and the refuse of the saw-mills feeds the fires under the salt-pans.

The following table (XVI.) shows the value of the metallic products of the United States for the years 1882, 1883, 1884, and 1885, as reported by the chief of the Division of Mining Statistics of the United States Geological Survey :—

	1882.	1883.	1884.	1885.
Pig-iron	\$106,336,429	\$91,910,200	\$73,761,624	\$64,712,400
Silver	46,800,000	46,200,000	45,600,000	51,600,000
Gold	32,500,000	30,000,000	30,800,000	31,801,000
Copper	16,038,091	18,064,807	18,106,162	18,292,999
Lead	12,624,550	12,322,719	10,587,042	10,469,481
Zinc	3,646,620	3,811,106	3,422,707	3,539,856
Mercury	1,487,042	1,253,632	936,327	979,189
Nickel	309,777	52,920	48,412	191,758
Antimony	12,000
Platinum	600	600	450	187
Aluminium	875	1,350	2,550
Total	\$219,755,109	\$203,116,859	\$186,414,074	\$181,589,365

The value of the iron is the spot value; that of the gold and silver the coining value; that of the copper, lead, and zinc the value at New York; and that of the mercury the value at San Francisco.

The total values of the mineral products of the United States for the same years are returned on the same authority as amounting respectively to \$235,461,580, \$249,049,889, \$226,800,674, and \$246,931,991.

PART III.—POLITICAL GEOGRAPHY AND STATISTICS.

Copyright, 1888, by Francis A. Walker.

POPULATION.

Growth of the population.

The population of the English colonies in North America was at no time definitely ascertained. In his *History of the Constitution*, Mr G. T. Curtis presents a table showing the estimated numbers in the several States as that used by the "Federal Convention" of 1787. By this the aggregate population is put at 2,781,000. By the first census of the United States, however, taken in 1790, the population was ascertained to be then 3,929,214. The second census, in 1800, showed a population of 5,308,483; and the third, that of 1810, showed another prodigious advance, the register reading 7,239,881. An important prediction in the history of population is that of Elkanah Watson, of New York, who in 1815 undertook to project the population of the United States from 1820 to 1900. The following are his figures for the period 1820 to 1850 (Table I.), in comparison with the actual results of the successive enumerations:—

Watson's predictions.

	1820.	1830.	1840.	1850.
Watson	9,625,734	12,833,645	17,116,526	23,185,368
The census	9,632,822	12,866,020	17,069,453	23,191,876
Watson's error	-8,088	-32,375	+47,073	-6,508

No similar series of statistical predictions ever attained such a degree of verification, or commanded equal interest or admiration. But quite as remarkable as the fulfilments of the earlier estimates have been the failures in the later ones, as shown by the corresponding figures for 1860 to 1900 (Table II.):—

	1860.	1870.	1880.	1890.	1900
Watson	31,753,824	42,328,432	56,450,241	77,266,989	100,355,985
Census	31,443,321	38,558,371	50,155,783		
Watson's error	+310,503	+3,770,061	+6,294,458		

Conditions of increase.

Watson's estimates came so true during the earlier decades because of the remarkable steadiness of the conditions then controlling population. In 1790 there were about 600,000 white families in the United States. Speaking broadly, there were few very rich, and, except from the effects of intemperance or the premature death of the breadwinner, there were few very poor. Food was abundant. Both social traditions and the religious beliefs of the people encouraged fecundity. The country enjoyed domestic tranquillity. All this while, too, the land was but partially settled. Mechanical labour was scarce, and even upon the farm it was difficult to command hired service, almost the only farm labourers down to 1850, in the north, being young men who went out to work for a few years to get a little ready money to marry upon. The conditions recited are such as would allow population to expand without restriction. The change that was inevitable came between 1840 and 1850. That the reduction in the birth-rate coincided with a cause which was regarded as certain to quicken the increase of population, namely, the introduction of a vast body of fresh peasant blood from Europe, affords another instance in proof that, even in this matter of population, moral are far more potent than physical causes.

The accessions between 1840 and 1850 from Ireland and Germany were enormous, the total immigration rising to 1,713,251 against 599,125 during the decade preceding, and against only 143,439 from 1820 to 1830. And these people came in condition to breed with unprecedented rapidity, under the stimulus of an abundance, in regard to food, shelter, and clothing, such as the most fortunate of them had never known. Yet, in spite of these accessions, the population of the country realized a slightly smaller proportion of gain than when the foreign arrivals were almost insignificant.

The change which produced this falling off from the traditional rate of increase, namely, about 3 per cent. per annum, was that from the simplicity of the early times to comparative luxury, involving a rise in the standard of living, the multiplication of artificial necessities, the extension of a paid domestic service, the introduction of women into factory labour. For a time the retardation of the normal rate of increase among the native population was concealed from view by the extraordinary immigration. During the decade 1850 to 1860 the foreign arrivals rose to the enormous total of 2,579,580, till it came about that almost one-seventh of the population of the country consisted of persons born abroad. And among this class no influence was yet exerted in restriction of population. Yet in spite of the arrival of 4,292,831 foreigners between 1840 and 1860, of whom 3,500,000 survived at the latter date, having had three (perhaps four) million children born to them on the soil, the census returns of 1860 showed a falling off from Watson's prediction of 310,503. At the time that prediction was made (1815) the arrivals at ports of the United States had averaged about 5000 per annum. Had the reinforcement from the outside been enhanced

only proportionally to the increase within, the figures for 1860 would have found Watson's estimate wrong by several millions.

The ten years from 1860 to 1870 witnessed the introduction of a new force operating to bring down the rate of national increase, namely, the war of secession. The superintendent of the ninth census, 1870, presented a computation of the effects of this cause,—first, through direct losses, by wounds or disease, either in actual service of the army or navy, or in a brief term following discharge; secondly, through the retardation of the rate of increase in the coloured element, due to the privations, exposures, and excesses attendant upon emancipation; thirdly, through the check given to immigration by the existence of war, the fear of conscription, and the apprehension abroad of results prejudicial to the national welfare. The aggregate effect of all these causes was estimated as a loss to the population of 1870 of 1,765,000. Finally, the temporary reduction of the birth-rate, consequent upon the withdrawal of perhaps one-fourth of the natural militia (males of 13 to 44 years) during two-fifths of the decade, may be estimated at perhaps three-quarters of a million. From these computations it would appear that, had the war of 1861–65 not broken out, the population of 1870 would still, in spite of accessions from abroad and of the quickened fecundity of the newly arrived elements, have shown a large deficiency from the numbers estimated by Watson.

The tenth census put it beyond doubt that economic and social forces had been at work, reducing the rate of multiplication. The ascertained population of 1880 was 50,155,783, against the estimated 56,450,241. Yet no war had intervened; the industries of the land had flourished; the advance in accumulated wealth had been beyond all precedent; immigration had increased to 2,944,695 for the decade. It is hazardous to speak of the future; but the most reasonable computation which can at present be made fixes the population of 1900 at about eighty millions, or twenty millions less than the estimate of Watson.

The achievement of independence found the people of the United States owning the entire country between the Gulf and the Great graphical Lakes, excepting only Florida, as far to the west as the Mississippi; process but the actual settlements were, with a few minor exceptions, confined to a narrow strip of territory along the Atlantic shore. The national depth of settlement, from the coast inland, varied greatly, ranging growth from what would be involved in the mere occupation of the shore See Plate for fishing purposes to a body of agricultural occupation extending VII. back to the base of the great Atlantic chain.

If we trace the western boundary of the body of continuous settlement at that time, we find, beginning at the north-east, sparse settlements extending along the entire seaboard to the New Hampshire line. The southern two-thirds of New Hampshire and nearly all Vermont were thinly covered by population. Reaching New York, the line of population branched off from the Hudson, north of the Mohawk, the westward tide flowing through a broad gap between the Adirondacks and the Catskills, which constitutes the northernmost of four main paths along which migration has historically taken place. Spreading over central New York, population had already covered the valley of the Mohawk and the region of the interior lakes. In Pennsylvania population had spread north-westward, occupying not only the Atlantic plain but also, with sparse settlements, the region traversed by the numerous parallel ridges of the eastern portion of the Appalachians. We omit, for the moment, consideration of the settlements around the junction of the Allegheny and the Monongahela rivers, representing an overflow through the second of the four great channels of population,—that, namely, which crosses southern Pennsylvania, western Maryland, and northern Virginia, parallel to and along the course of the upper Potomac. Omitting then this, which we may term the Pittsburgh group, we find, in Virginia, that sparse settlements had in 1790 extended westward beyond the Blue Ridge, and into what is now West Virginia, on the western slope of the Alleghany Mountains, while another narrow tongue of population had penetrated south-westwards, down to the head of the Tennessee river, in the great Appalachian valley, having found out the third of the four main channels alluded to. In New Carolina settlement was still limited by the base of the Appalachians. Georgia was as yet, owing to the presence of Indian tribes, only occupied to the depth of about two counties along the Savannah river. The reservations of the Red Men still prevented population from moving westward along the fourth of the great natural paths alluded to,—namely, that around the southern end of the Appalachian chain.

In the preceding rapid survey of the new nation four groups have been omitted,—the first, the Pittsburgh group, in south-western Pennsylvania; the second, the smallest, in West Virginia, upon the Ohio and Kanawha rivers; the third, and by far the largest, in northern Kentucky, upon the Ohio river, comprising about 11,000 square miles; and the fourth upon the Cumberland river, in Tennessee. The existence of these outlying groups of

population in 1790 bore witness to the daring and even reckless courage of the American pioneer.

1790. In addition there were in 1790 a score or more of small posts or incipient settlements, mainly of French origin, scattered over what was then an almost unbroken wilderness. Among these were Detroit, Vincennes, Kaskaskia, Prairie Du Chien, Machinac, and Green Bay. The entire settled area at the first census is computed to have been 239,935 square miles, which, with an aggregate population of 3,929,214, would yield an average density of 16.4 persons to the square mile. The centre of population, as that phrase is commonly understood, rested east of Baltimore.

1800. The census of 1800 showed a total settled area computed at 305,708 square miles, including all outlying tracts. As the population had risen to 5,308,483, the average density of settlement had become 17.4. The centre of population had moved 41 miles west, along the 39th parallel of latitude.

1810. The map of 1810 shows a vast change, owing to the acquisition of Louisiana from France; the settled area was 407,945 square miles, which, with an ascertained population of 7,239,881, gave an average of 17.7 persons to the square mile. It is remarkable that the American people, in nearly doubling their numbers between 1790 and 1810, only increased the average density of settlement from 16.4 to 17.7. At the latter date we find the hills of western New York now almost entirely covered with population, which has spread along the southern shore of Lake Erie, well over into Ohio, effecting a junction with the previously existing body of settlement about the forks of the Ohio. The occupation of that river has become complete from its source to its mouth, with the exception of small gaps below the entrance of the Tennessee. The early Kentucky settlements have expanded in every direction, until almost the entire State is covered, while that body of population has been extended southwards to the Tennessee, in what is now northern Alabama. In Georgia settlement is still held back by the presence of the Creek and Cherokee Indians, although a treaty with the former tribe in 1802 has opened up portions of the State, which have been eagerly occupied. In Ohio the movements of population northward from the river of that name and westward from Pennsylvania have carried forward the line of settlement, until it comprises two-thirds of the State. Michigan and Indiana, still Territories, remain virgin soil, with the exception of a little strip around Detroit, and a small area in the south-western part of Indiana. St Louis has been transferred, by the purchase of Louisiana, from a foreign jurisdiction to that of the United States, and has become an important centre of population, settlements having spread from it northward to above the mouth of the Missouri, and southward, along the Mississippi, to the mouth of the Ohio. At the mouth of the Arkansas is found a similar body of population. Looking still farther south, settlements are observed in the newly organized Territory of Orleans, extending across the Mississippi to its left bank, and reaching up to the site of Vicksburg.

1820. In 1820, at the fourth census, the population had become 9,633,822; the area of settlement had reached 588,717 square miles, yielding an average density of 18.9. The effect of the westward movement during the decade had been to move the centre of population 50 miles, still on the 39th parallel.

1830. In 1830 the area of settlement was 632,717 square miles, yielding, with an aggregate population of 12,866,020, an average density of 20.3. The centre of population had passed westward only 30 miles, the energies of the people having been given largely to filling up the already included areas. The most noticeable changes are in the south. In Georgia the settlements have spread westward, across the entire breadth of the State, where they have struck against the barrier of the diminished Creek reservation. Stopped at this point, they have moved downwards into the south-west corner of the State, and over the boundary line into Florida, recently acquired from Spain. No general advance is to be noted in Mississippi, owing to the continued presence of the Choctaw and Chickasaw nations. The Alabama group has widened and deepened, until perhaps two-thirds of the State is covered. In Mississippi the chief growth has been through a broad belt, up the river of the same name, reaching to the present site of Kansas City. Population has progressed northward in Illinois, until more than half the State is covered; while Indiana and Ohio have greatly reduced their vacant areas.

1840. The settled area of 1840 was 807,292 square miles; the population was 17,069,453, the average density 21.1. The centre of population had moved 55 miles, almost exactly due west. The most marked changes during the ten years had been in Georgia, Alabama, and Mississippi, whence the Indian tribes—Cherokees, Creeks, Chickasaws, and Choctaws—had been removed to the Indian Territory. Now, at last, we see population taking the southernmost of the four western routes of migration,—that round the lower end of the Appalachian chain. In northern Illinois, the Sac and Fox and Pottawatamie tribes having been removed to the Indian Territory, their country has been promptly taken up; and we now find settlements carried over the whole extent of Indiana and Illinois, and northwards across Michigan and Wisconsin, as far as the 43d parallel. Population has passed the Mississippi into

Iowa Territory, and occupies a broad belt up and down that stream. In Missouri the settlements have spread northwards from the Missouri river nearly to the boundary of the State, and in the opposite direction until they cover most of the southern portion, making connexion with the settlements in Arkansas. Population has largely increased in Florida; but the southern portion of the State remains unoccupied, owing to the hostility of the Seminole Indians.

Between 1840 and 1850 the limits of the United States had been 1850. greatly extended by the annexation of Texas and the territory ceded by Mexico in the treaty of Guadalupe Hidalgo, these acquisitions embracing an area larger than the original area of the United States as defined by the treaty of 1783. The frontier of population now rests on the Missouri through a great north and south extent; and this date thus marks the natural division of the history of population in the United States into two parts. The map of 1850 does indeed show a few settlements on the newly acquired Pacific coast, sparsely covering perhaps 30,000 square miles, with mining camps from a few weeks to a year old, comprising in all about 100,000 souls. But these small and distant groups may, in a survey like the present, be disregarded. In this great journey of the English race to the Missouri we have seen the population increase from 3,929,214 to 23,191,876; the settled area has increased from 239,935 square miles to 979,249. The territory of the United States has grown, through purchase and war, from 827,844 to 2,980,961 square miles. The original thirteen States have become thirty. The centre of population has moved westward, during sixty years, over the space of 276 miles, notwithstanding the deepening of agricultural settlement in the older portions of the country and the growth of large commercial towns upon the seaboard, which have raised the average density to 23.7 persons to the square mile.

In 1860 the population of the Pacific coast settlements (about 1860. 100,000 in 1850) had risen to about 620,000, covering sparsely about 100,000 square miles. In the east the great fact observed is the extension of settlement, for the first time, beyond the line of the Missouri. The movement up the slope of the great plains has begun. Into Kansas and Nebraska, especially the former, settlers are pouring rapidly, under the influence of the fierce struggle which is being waged to determine the political character of those Territories. Population has reached even beyond the 97th meridian. In the south Texas has filled up still more rapidly, its extreme settlements reaching to the 100th meridian. The small groups about St Paul, in Minnesota, have spread in all directions, after forming a broad band of union with the main body of population, down the line of the Mississippi. In Iowa population has crept steadily north-westward, along the course of the drainage, until the State is nearly covered. Following up the Missouri, settlers have crossed into the south-eastern corner of the present Territory of Dakota. In Wisconsin the settlements have moved at least one degree farther north. In the upper peninsula of Michigan the little settlements which appeared in 1850, in the upper region around Keweenaw Point, have extended and increased in density as that mining region has developed in importance. The hitherto unsettled regions in southern Missouri, north-eastern Arkansas, and north-western Mississippi have become sparsely covered. The entire occupied area of 1860 is 1,194,754 square miles; the population is 31,443,321, and the average density 26.5. The centre has moved 81 miles westward since 1850.

The year 1870 found the nation undivided, with an aggregate 1870. population of 38,558,371, occupying 1,272,239 square miles, the average density being 30.3. The new Cordilleran and Pacific coast settlements, beyond the 100th meridian, comprising about 1,000,000 souls, occupying about 120,000 square miles, have arranged themselves, rudely, in three longitudinal belts. The most eastern of these lies in central Colorado, New Mexico, and Wyoming, and along the eastern base of the Rocky Mountains. Population was first largely attracted thither in 1859 and 1860 by the discovery of mineral deposits, and has been retained there by the richness of the soil and the abundance of water for irrigation. The second belt is that of Utah, settled by the Mormons. This community differs radically in character from other Rocky Mountain settlements, being essentially agricultural, the mining industries having been discountenanced as tending to fill their "Promised Land" with Gentile adventurers. The settlements here in 1870 extended from southern Idaho southward, through central Utah, into northern Arizona. With the exception of the two considerable towns of Ogden and Salt Lake, they consisted mainly of scattered hamlets and small villages, around which were grouped the farms of the several communities. The third belt is that in the Pacific States and Territories, extending from Washington Territory southward to southern California, and eastward to the systems of "Sinks," so called, in western Nevada. This highly complicated body of population owes its existence to the mining industry. Beginning in 1849, it has grown through successive mineral discoveries, although more than one of its chief seats in earlier days have long since become deserted camps, more dreary even than before the white man came. Latterly the value of this region to the agriculturist has been recognized, and the occupations of the inhabitants are undergoing a

marked change. These three longitudinal belts comprised nine-tenths of the population of 1870 which was west of the general frontier line. The remainder were scattered about in the valleys and on the mountains of Montana, Idaho, and Arizona, in military posts, in isolated mining camps, and on cattle ranches.

In the east the traditional westward movement proceeded at less than its usual rate during 1860-70. Whereas the centre of population moved 81 miles in 1850-60, it accomplished a journey of only 42 miles in the succeeding decade. In part this was due to the discouragement of pioneer enterprise by the state of war, portions of the frontier being involved in Indian hostilities, or becoming the scene of guerilla atrocities, all the way from Minnesota to Arizona; in part, to the absorption into the army of the restless portion of the population which had been wont to lead the race in opening up new regions. In larger part, however, it was due to the prodigious growth, under the artificial encouragement afforded by war, of the manufacturing industries of the east. Nevertheless, in southern Minnesota population had gone to the boundary of the State, and had poured up the Big Sioux river in south-eastern Dakota; Iowa had become entirely occupied; through Kansas and Nebraska population had moved westward, following, in general, the courses of the larger streams and of the newly constructed Pacific railroads.

1880.

The tenth census (1880) disclosed a population of 50,155,783. The first thing which strikes one is the vast extent of territory brought under occupation for the first time. The settled area has risen sharply to 1,569,570 square miles, so that, with nearly twelve millions added to the population, the average density of settlement has only increased from 30.3 to 32. The settlements in the Cordilleran regions and on the Pacific show enormous accessions of occupied territory. In the east we note changes which are far greater in absolute importance, though less conspicuous in comparison with the extent of previously existing settlement. In Kansas and Nebraska a broad tide has spread westward over the plains, annexing vast tracts before unoccupied. At several points the pioneer line has reached the boundary of the Humid Region, so that further extension must hereafter be governed by the supply of water in the streams. Hence we already see the principal river marked by long ribbon-like bands of population. In Minnesota and east Dakota the building of railroads and the remarkable wheat-producing capabilities of the region have caused a rapid development of population. Besides the agricultural region of east Dakota, we note the formation of a body of settlement in the Black Hills, in the south-west corner, the result of important discoveries of gold deposits. In Wisconsin the unsettled area has rapidly decreased as railroad construction has advanced. In the upper peninsula of Michigan the copper and iron interests, and the railroads which subserve them, have peopled a large extent of territory. In the lower peninsula not only have settlements surrounded the head of the peninsula, but there remains only a small body of unsettled lands in the interior, the vast pine forests having been swept away by the activity of the lumbering industry. In the south Texas has made great strides, through the extension of railroads and the development of the cattle and sheep interest. The unsettled area in the peninsula of Florida has decreased decidedly, while the vacant spaces heretofore seen along the upper coast of Florida and Louisiana have disappeared. The centre of population moved 58 miles westward between 1870 and 1880, making the total journey 457 miles since 1790.

The following tables (III., IV.) show the distribution of population by drainage basins and according to altitude:—

Popula-
tion ac-
cording

Height above Sea-Level, in Feet.	Population of the Group.	Per Cent. of Total Population within the Group.	Population below each Contour.	Per Cent. of Population below each Contour.
0-100	9,152,296	18.25	9,152,296	18.25
100-500	10,776,284	21.48	19,928,580	39.73
500-1000	19,024,820	37.93	38,952,900	77.66
1000-1500	7,904,780	15.76	46,857,680	93.42
1500-2000	1,878,715	3.75	48,736,395	97.17
2000-3000	664,923	1.33	49,401,318	98.50
3000-4000	128,544	.26	49,529,862	98.76
4000-5000	167,286	.33	49,697,098	98.99
5000-6000	271,217	.54	49,968,315	99.63
6000-8000	109,497	.22	50,077,812	99.85
8000 and over	77,871	.15	50,155,783	100

From the latter table it appears that nearly one-fifth of the inhabitants of the country lived below 100 feet, *i.e.*, along the immediate seaboard and in the swampy alluvial regions of the south; more than two-fifths lived below 500 feet, more than three-fourths below 1000 feet, while 97 per cent. lived below 2000 feet. Within the area below 500 feet is included nearly all that part of the population which is engaged in manufacturing, in the foreign commerce of the country, and in the culture of cotton, rice, and sugar. The interval between the 500 and the 1500 contours comprises the greater part of the prairie region and the grain-producing States of the north-west. The mean elevation of the surface of the United States is roughly computed at 2600 feet. The mean elevation of the actual population of 1880 is estimated at 700 feet.

At the date of the census of 1880 there were 6,679,943 persons Nativity residing in the United States who had been born in foreign lands, of the while at the same time there were 9,593,106 born in the United States who were living in other States than those of their birth. Generally speaking, the migrations of natives of the country have been, if not as usual directly along parallels of latitude, at least within the immediate zones of the individuals thus seeking new homes. Historically the statistics of the foreign elements are very incomplete. For only four censuses (1850-80) has the place of birth been returned in the enumeration of inhabitants. From 1850 backwards to 1820 we have only tables compiled from the passenger lists of vessels bringing in emigrants, data notoriously imperfect. Prior to 1820 there are only scraps of evidence. The following tables (V., VI.) show the arrivals at United States ports from 1820 to 1880 by decades, and the total population and total number of persons of foreign birth, with the proportions subsisting between the two, at each of the four censuses taken since this class of statistics began to be collected:—

	Total.	From Germany.	From British Isles.	From Other Countries.
1820-30	151,000	8,000	82,000	61,000
1830-40	599,000	152,000	283,000	164,000
1840-50	1,713,000	435,000	1,048,000	230,000

	Total Population.	Persons of Foreign Birth.	Per Cent. of Foreign.
1850	23,191,376	2,244,602	9.68
1860	31,443,321	4,138,697	13.16
1870	38,558,371	5,567,229	14.44
1880	50,155,783	6,679,943	13.32

The foreign-born have settled mainly between the 38th and 45th degrees of latitude; more than two-thirds of them are found between the 39th and 43d degrees.

The following table (VII.) shows the proportion per 10,000 of the natives of the foreign countries named:—

	1850.	1860.	1870.	1880.
Born in England and Wales.....	1,375	1,154	1,124	1,117
" Ireland.....	4,285	3,893	3,333	2,776
" Scotland.....	314	262	253	255
" Germany.....	2,601	3,063	3,037	2,944
" France.....	241	266	209	160
" British America.....	658	604	886	1,074
" Sweden and Norway.....	80	175	434	560
All other foreigners.....	446	563	724	1,114

The occupations most affected by foreigners will appear from the following table (VIII.), in which the units represent thousands:—

Persons born in	Engaged in all Occupations.	In Agriculture.	Personal or Professional Service.	Trade and Transportation.	Manufacturing, Mechanical, and Mining Industries.
United States.....	13,897	6,858	3,076	1,352	2,611
Germany.....	1,033	293	218	152	368
Ireland.....	979	140	415	138	284
Great Britain.....	467	104	80	56	226
Sweden and Norway.....	206	92	53	16	45
British America.....	351	73	91	33	154

In the following table (IX.) a few of the more important single occupations are selected for a further comparison:—

	Germany.	Ireland.	Great Britain.	Sweden and Norway.	British America.
Agricultural labourers.....	48	24	15	23	21
Farmers and planters.....	233	108	83	68	51
Boot and shoe makers.....	28	17	7	3	8
Textile operatives.....	9	39	32	1	44
Domestic servants.....	43	122	19	19	22
In iron and steel works.....	9	17	10	1	2
Labourers.....	114	225	31	28	50
Miners.....	10	25	47	5	6
Railroad employes.....	10	33	7	5	6
Traders and dealers.....	60	32	17	2	7

The question of the degree to which foreign elements have contributed to the remarkable growth of population in the United States has formed the subject of much discussion. In 1870 an important step towards the obtaining of adequate statistical data for the solution of the problem was made by ascertaining, in addition to the number of persons born abroad, the number having a foreign-born father or mother, or both. From this count it appeared that, while there were (1) 5,567,229 persons resident in the United States who were born in other countries, there were (2) 10,521,233 who had a foreign father, (3) 10,105,627 who had a foreign mother, (4) 9,734,845 who had both parents foreign, and (5) 10,892,015 who had one or both parents foreign.¹ Another and important step was taken in 1880, when the census office obtained the means of determining the number of persons one or both of whose parents had been born in each specified foreign country. From this enumeration it appeared that, while there were then in the United States (1) 6,679,943 persons who had themselves been born abroad, there were (2) 14,349,310 who had a foreign father, (3) 13,585,080 who had a foreign mother, (4) 13,011,646 who had both parents foreign, and (5) 14,922,744 who had one or both parents foreign. In addition to the above were found 33,252 persons, themselves born abroad, but of parents native to the United States. This would make the total number of persons born abroad, and of persons of foreign parentage, 14,955,996. This aggregate was distributed as follows among the chief nationalities (Table X.) :—

Persons having Irish fathers.....	4,529,523
" German ".....	4,883,842
" British ".....	2,039,803
" Scandinavian fathers.....	655,405
" British American fathers.....	939,247
" fathers born in other foreign countries than those specified.....	1,321,465
" native fathers and foreign mothers.....	573,434
Foreign persons, having both parents native.....	33,252
Total.....	14,955,996
Persons having Irish mothers.....	4,448,421
" German ".....	4,557,639
" British ".....	1,790,200
" Scandinavian mothers.....	631,309
" British American mothers.....	931,408
" mothers born in foreign countries other than those specified.....	1,226,113
" native mothers and foreign fathers.....	1,337,664
Foreign persons, having both parents native.....	33,252
Total.....	14,955,996

Comparing these results with the total number of persons from each specified foreign country resident in the United States, we find that, for every 1000 persons living in the United States who were born in Ireland, there were in 1880 2442 who had an Irish father, 2387 who had an Irish mother; for every 1000 persons born in Germany there were 2483 who had a German father, 2306 who had a German mother; for every 1000 persons born in Great Britain there were 2223 who had a British father, 1941 who had a British mother; for every 1000 persons born in Sweden or Norway there were 1690 who had a Swedish or Norwegian father, 1671 who had a Swedish or Norwegian mother; for every 1000 persons born in British America there were 1310 who had a British American father, 1292 who had a British American mother.

These ratios do not accurately represent the comparative fecundity of the foreign population, unless reference be had to the periods of time during which the several elements have respectively formed an important part of the population of the United States. The fact that for every 1000 persons born in Ireland there were in 1880 2442 persons (including of course the 1000 mentioned), who had an Irish father, while for every 1000 British Americans there were only 1310 who had a British American father, would seem to indicate that the Irish are vastly more prolific than the British Americans. The disproportion is, however, mainly due to the fact that the Irish residents have lived in the country for a very much longer period of time than the British Americans. Thus, of every 10,000 foreigners in the United States in 1850, 4285 were Irish, while only 658 were British Americans. In 1880, out of every 10,000 foreigners, only 2776 were Irish, 1074 were British Americans. Again, it will have been noted that, in every case mentioned, there are more of persons having a foreign father than of persons having a foreign mother. This is true regarding each nationality, not only for the country, but for each State, and is due to the fact that immigration is predominantly of males.

The first census (1790) showed the number of coloured persons to be 757,208, the coloured element thus constituting a larger proportion of the population than ever after, i.e., 19·3 per cent. By 1800 the coloured element had increased absolutely to 1,002,037, being a gain per cent. of 32·32, but had declined relatively to 18·9 per

cent. of the entire population. By 1810 it had reached 1,377,808, a gain of 37·05 per cent. upon its own numbers in 1790; it had also advanced towards its former share of the population, being 19 per cent. of the whole. By 1820 the number had risen to 1,771,656, a gain of 28·58 per cent. in ten years; the share of this element in the total population had sunk to 18·4 per cent. By 1830 the number had increased to 2,323,642, a gain of 31·44 per cent.; the ratio to the total population had sunk to 18·2. By 1840 the total numbers had risen to 2,873,648, a gain of 23·4 per cent. (16·8 per cent. of the whole population). In 1850 the number was 3,638,808 (13·3 of whole population), a gain of 26·62 per cent. in ten years. On the threshold of the civil war in 1860 the number had risen to 4,441,830 (14·1 per cent. of whole population), being a gain of 22·06 per cent. in ten years. The enumeration of the coloured population in 1870 was subsequently proved to have been partial and inaccurate in many parts of several Southern States. The number returned was only 4,880,009 (12·7 per cent. of total population), a gain of only 9·86 per cent. in ten years. In 1880 the number was 6,580,793 (13·1 of the whole), an increase of 34·85 per cent. over 1870.

The following table (XI.) summarizes the facts of gain per cent. within the coloured population by ten-, twenty-, and thirty-year periods, from 1790 to 1880:—

	Coloured Population.	Per Cent. of Total Population.	Increase per Cent.		
			10 Years.	20 Years.	30 Years.
1790	757,208	19·3
1800	1,002,037	18·9	32·32
1810	1,377,808	19	37·05	81·96	...
1820	1,771,656	18·4	28·58	76·8	133·97
1830	2,323,642	18·2	31·44	69·01	132·39
1840	2,873,648	16·8	23·4	62·2	108·56
1850	3,638,808	13·3	26·62	56·26	105·39
1860	4,441,830	14·1	22·06	54·57	90·74
1870	4,880,009	12·7	9·86	34·11	69·82
1880	6,580,793	13·1	34·85	48·15	80·85

The coloured people, all but an inconsiderable fraction, live between the 29th and 40th degrees of latitude. In this respect, the foreign and the coloured elements are largely complementary. Only between the 38th and 40th parallels are both elements found in considerable numbers. In longitude the coloured are much more widely spread than are the foreigners. Again, the temperature and rainfall groups which contain one of these elements largely seldom embrace any considerable portion of the other. Thus, it appears that, while more than 87 per cent. of the foreign-born live in regions having a mean annual temperature of 40° to 55° F., more than 93 per cent. of the coloured reside in regions having a mean annual temperature of 50° to 70°. In the region having a rainfall of about 60 inches annually, the coloured form no less than 43 per cent. of the total, and in the next grade 36·5 per cent., while in the region having a rainfall of 50 to 55 inches more than half the inhabitants are coloured. Where the rainfall is less than 45 inches the coloured population falls below the average, in some cases very far below. Not less than 85 per cent. of the coloured are found within regions between 40 and 60 inches. The foreign population, on the other hand, is chiefly grouped in regions between 30 and 50 inches, those regions containing nearly 85 per cent. of the foreign-born. Further, only 14·10 per cent. of the foreign population live in the regions raised 100 to 500 feet above the sea, while within those regions are found not less than 44·95 per cent. of the coloured population.

The question of the future of the coloured race in the United States mainly depends on the answer to a prior question, whether the fact of the concentration in so great a degree of this element upon the lands at once very hot and very moist, which has actually taken place, is due to the superior attractions of cotton-planting in the past and even in the present, or represents also the special physiological aptitudes of the race. The enormous apparent increase in this element during 1870 to 1880 led some persons to project a line of ascent which would, in a few generations, cause the continent to be peopled almost entirely by members of the African race. Such predictions are as idle as were those of the speedy extinction of the coloured population after the disparaging but erroneous results of the census of 1870 were published. Inasmuch as twenty-year periods have, from the beginning, shown a steady successive decline in the rate of increase among the coloured population (see Table XI.), it would seem that some positive reason should be shown for anticipating any higher rate for the future than that of 54·57 for 1840-60. Such a rate of increase among the coloured people would steadily reduce the share of that element in the population of the country, bringing its numbers up to about ten millions in 1900 out of a not improbable population of eighty millions. Whether there is really room, economically speaking, for so large a coloured population, considering the limited area of the lands, already fairly well occupied, within which alone that race has any marked advantage over the whites by reason of their physiological adaptation to the climate, and considering the

¹ The reader will understand that these sums are not to be added together, as has been done in some statistical publications, yielding an aggregate somewhat larger than the entire population of the United States at the time. No. 1 is included in No. 4, which is itself included in both Nos. 2 and 3, which are in turn included in No. 5, which is the outside statement of that portion of the population whose members were either themselves born abroad, or who had either a father or mother born abroad.

industrial advantages which the white race enjoy wherever the climate conditions are equally favourable, may be gravely doubted.

Cities.

The growth of city populations during the ninety years embraced by the ten successive censuses of the United States has been little less remarkable than the increase of population throughout the country as a whole. The following table (XII.) gives the aggregate for cities of 8000 inhabitants and upwards from 1790 to 1880:—

	Population of United States.	Population of Cities.	Urban Population in each 100 of the Total.
1790	3,929,214	131,472	3.3
1800	5,306,433	210,873	3.9
1810	7,239,881	356,920	4.9
1820	9,633,822	475,135	4.9
1830	12,866,020	864,509	6.7
1840	17,069,453	1,453,994	8.5
1850	23,191,876	2,897,586	12.5
1860	31,443,321	5,072,256	16.1
1870	38,558,371	8,071,875	20.9
1880	50,155,788	11,318,547	22.5

In 1880 there were 286 cities with over 8000 inhabitants, and the following twenty exceeded 100,000:—New York, N.Y., 1,206,299; Philadelphia, Pa., 847,170; Brooklyn, N.Y., 566,663; Chicago, Ill., 503,185; Boston, Mass., 362,839; St Louis, Mo., 350,518; Baltimore, Md., 332,313; Cincinnati, O., 255,139; San Francisco, Cal., 233,959; New Orleans, La., 216,090; Cleveland, O., 160,146; Pittsburgh, Pa., 156,889; Buffalo, N.Y., 155,134; Washington, D.C., 147,293; Newark, N.J., 136,508; Louisville, Ky., 123,758; Jersey City, N.J., 120,722; Detroit, Mich., 116,340; Milwaukee, Wis., 115,587; Providence, R.I., 104,857.

The urban population of the United States is predominantly sustained by manufactures and mechanical industry rather than by commerce. Taking for the purposes of this analysis the fifty largest cities, we have an aggregate of 3,083,172 workers, of whom 32 per cent. are engaged in personal and professional services, 24 per cent. in trade and transportation, 43 per cent. in manufactures and mechanical industry, the remaining 1 per cent. being employed in agriculture, as nurserymen, florists, market-gardeners, &c. Of the total body of workers reported 77 per cent. are males, 23 females. Again, 3½ per cent. are under 16 years of age, 3 per cent. are over 60, 93½ per cent. are between 16 and 60.

The proportion of workers to population varies greatly in American cities, according to the industries pursued, according to the constituents of the population, according to age and sex, and according to certain social causes affecting the employment of women and young children.

Occupations of the people.

The American census took no account of the occupations of the people till 1850, when the occupations of the free male inhabitants over 15 years of age were ascertained. In 1860 the statistics were made to include the gainful occupations of free women as well, but the exclusion of the entire slave population from the account, together with defects of classification due to the inherent difficulties of the work, make it impossible to institute satisfactory comparisons with statistics subsequently obtained. At the ninth and tenth censuses (1870 and 1880) special efforts directed to this end, aided by the great progress made of recent years in industrial organization and by the abolition of slavery, resulted in statistical accounts which afford a fair view of the occupations of the people at those dates.

The census of 1870 gave the number of people pursuing gainful occupations as 12,505,923, being 32.43 per cent. of the total population, 44.3 per cent. of the total population above ten years of age. In 1880 the corresponding number was 17,392,099, being 34.68 per cent. of the entire population, 47.31 per cent. of the population above ten years of age. This increase means a larger engagement of women and children in labour outside the family. The division of the grand total of 1880 among the four principal groups of occupations, with the further distinction of sex, appears in the following table (XIII.):—

Classes.	Persons Occupied.	Males.	Females.
Agriculture.....	7,670,493	7,075,983	594,510
Personal and professional services.....	4,074,238	2,712,943	1,361,295
Trade and transportation.....	1,810,256	1,750,892	59,364
Manufacturing, mechanical, and mining.....	3,837,112	3,205,124	631,988
All occupations.....	17,392,099	14,744,942	2,647,157

Of these, 825,187 males and 293,169 females were from 10 to 15 years of age, 12,986,111 males and 2,283,115 females from 16 to 59, and 933,644 males and 70,873 females 60 and upwards.

It appears that 7,670,493 persons were in 1880 employed in agriculture, constituting 44.1 per cent. of the whole number, against 47.3 in 1870, — a slight relative decline in this class during the decade. 4,225,945 persons reported themselves as farmers or planters. This agrees well with the number of farms and plantations returned on the agricultural schedule, i.e., 4,008,907. 3,323,876 persons report themselves as farm labourers, while about 120,000 are returned as apirists, dairymen, florists, gardeners, nurserymen,

stock-drovers, turpentine farmers, &c. Agriculture still remains the predominant industry of the United States, employing nearly half the working population, and, since a greater number of persons are dependent upon the average farmer or farm labourer than upon the average factory operative or domestic servant, furnishing subsistence to considerably more than half the people.

The number of persons engaged in mechanical labour and in manufacturing and mining pursuits in 1880 was 3,837,112, — 22 per cent. of the total, against 21.6 per cent. in 1870.

The number of persons engaged in trade and transportation was in 1880 1,810,256, being 10.4 per cent. of the total. Between 1860 and 1870, with an increase in population of 22.8 per cent., the class engaged in trade and transportation gained 44 per cent., a result fairly attributable to the profits of middle-men, and the multiplication of stores, shops, and stands of every description, consequent upon the circulation of an irredeemable and fluctuating currency.

The last grand group of occupations to be mentioned is that characterized by the rendering of personal or professional services. This group in 1880 embraced 4,074,238 men, women, and children, or 23.4 of all connected with gainful vocations, against 21.4 per cent. in 1870. The occupations within this group exhibit a wide range of character. We have at the one end the teacher, the Government official, the artist, the clergyman, the physician; at the other, the barber, the boot-black, the household drudge. The most important class of this group is that known as labourers, without further designation. This class, in the successive census reports, has always been large, doubtless too large for the facts of the case, since it seems probable that no inconsiderable share of these labourers are connected with agriculture or trade or some branch of manufacturing industry with sufficient definiteness to justify their being returned under one or other of those groups. The number reported under this title in 1850 was 909,786; in 1860, 969,801; in 1870, 1,031,666; in 1880, 1,859,223.

The number of domestic servants in 1880 was 1,075,655, against 975,734 in 1870. It might have been expected that the general increase of luxury and refinement during the preceding decade must have caused a large proportional increase in domestic service. Yet we find the number of domestic servants to have increased but 10 per cent., while population has grown 30 per cent. The only fact indicated by the table of occupations which serves at all to account for this failure of domestic service to keep pace with population is that the number of bakers has increased more than 50 per cent. during the decade, while the number of laundrymen and laundresses has grown from 60,906 to 121,942, showing that some part at least of the work formerly done in private houses is now done in shops. Yet we cannot fail to be struck with the fact that, while there was in 1870 1 servant to 7.76 families, 1880 found no more than 1 servant to 9.24 families.

The geographical distribution of domestic service throughout the United States is very irregular, the proportion between families and servants ranging from 2.5 families to 1 servant in the District of Columbia up to 24.8 families to 1 servant in Arkansas. The largest proportion of domestic servants is found in a group in the central Atlantic region, — Maryland, Delaware, Virginia, and the District of Columbia, where slavery formerly prevailed more as a social and political than as an industrial institution. Thus Maryland has 1 servant to 4.9 families, Delaware 1 to 5.3, Virginia 1 to 5.7.

In 1870 the number of families returned was 7,579,363, the number of persons to a family being 5.09; the number of dwellings was 7,042,833, with 5.47 persons to a dwelling. In 1880 the total number of families returned was 9,945,916, the number of persons to a family being 5.04; the number of dwellings was 8,955,812, with 5.6 persons to a dwelling. In 1880 the number of persons to a family ranged from 3.94 in Montana to 5.54 in West Virginia; the number of persons to a dwelling ranged from 4.24 in Idaho to 6.68 in Rhode Island. Examination of the tables relating to the 100 largest cities in 1880 shows that the number of persons to a family ranges from 4.23 in Memphis to 5.99 in Denver. In general, the Southern cities rule low in this respect. The range as to the number of persons to a dwelling, among the cities of the United States, is much greater than in the case of persons to a family. Memphis has but 4.68 persons to a dwelling; New York has as many as 16.37. The other instances of a low proportion are Lancaster, Pa., 5.02; Davenport, Iowa, 5.04; Camden, N.J., 5.05; Sacramento, 5.07. The other instances of a high proportion are Hoboken, 11.50; Holyoke, Mass., 10.52; Brooklyn and Cincinnati, 9.11; Manchester, N.H., 9.09; Worcester, 8.79; Fall River, 8.75; Jersey City, 8.59; Lawrence, 8.5; Boston, 8.26; Chicago, 8.24; Troy, 8.16; St Louis, 8.15. The other large cities show the following proportions: — Philadelphia, 5.79; New Orleans, 5.95; Baltimore, 6.54; San Francisco, 6.86. The remarkably low proportion, considering the population, which obtains in Philadelphia is due to the admirable manner in which that city has been built up, largely under the system of ground rents, little known in other cities.

AGRICULTURE.

Rapid
extension
of settle-
ments.

Agriculture has been the chief and most characteristic work of the American people, that in which they have achieved the greatest results in proportion to the resources at command, that in which their economic superiority has been most strikingly manifest. In ten years from 1790, the mean population of the period being 4,500,000, 65,000 square miles were for the first time brought within the limits of settlement, crossed with roads and bridges, covered with dwellings, both public and private, much of it also cleared of primeval forest; and this in addition to keeping up and improving the whole extent of previous settlements, and building towns and cities at a score of favoured points. In the next decade, the mean number of inhabitants being about 6,500,000, population extended itself over 98,000 square miles of absolutely new territory,—an area eight times as large as Holland. Between 1810 and 1820, besides increasing the density of population on almost every league of the older territory, besides increasing their manufacturing capital twofold, in spite of a three years' war, the people of the United States advanced their frontier to occupy 101,000 square miles, the mean population being 8,250,000. Between 1820 and 1830 124,000 square miles were brought within the frontiers and made the seat of habitation and cultivation; between 1830 and 1840, 175,000 square miles; between 1840 and 1850, 215,000 square miles. The war of secession, indeed, checked the westward flow of population, though it caused no reflux; but between 1870 and 1880 territory embracing 297,000 square miles was reclaimed from the wilderness and the desert, was divided into farms, crossed everywhere by roads and here and there by railroads, and dotted over with dwellings.

Character
of the
agri-
cultural
class.

That which has allowed this great work to be done so rapidly and fortunately has been, first, the popular tenure of the soil, and, secondly, the character of the agricultural class. At no time have the cultivators of the soil north of the Potomac and Ohio constituted a peasantry in the ordinary sense of that term. They have been the same kind of men, precisely out of the same homes, generally with the same early training, as those who filled the learned professions or who were engaged in manufacturing or commercial pursuits. Switzerland and Scotland have, in a degree, approached the United States in this particular; but there is no other considerable country where as much mental activity and alertness has been applied to the cultivation of the soil as to trade and manufactures.

Pioneer-
ing in-
geni-
uity.

But even the causes which have been adduced would have failed to produce such effects but for the exceptional inventive ingenuity of the American. The mechanical genius which has entered into manufactures in the United States, the engineering skill which has guided the construction of the greatest works of the continent, have been far exceeded in the hurried "improvements" of the pioneer farm; in the housing of women, children, and live stock and gathered crops against the storms of the first few winters; in the rough and ready reconnaissances which determined the "lay of the land" and the capabilities of the soil; in the preparation for the thousand exigencies of primitive agriculture. It is no exaggeration to say that the chief manufacture of the United States, thus far, has been the manufacture of four million farms, comprising 540,000,000 acres.

System of
cultiva-
tion.

The people of the United States, finding themselves on a continent containing an almost limitless extent of land of fair average fertility, having at the start but little accumulated capital and urgent occasions for the economy of labour, have elected to regard the land in the earliest stages of occupation as practically of no value, and to regard labour as of high value. In pursuance of this view they have freely sacrificed the land, so far as was necessary, in order to save labour, systematically cropping the fields on the principle of obtaining the largest results with the least expenditure, limiting improvements to what was demanded for immediate uses, and caring little about returning to the soil an equivalent for the properties taken from it in the harvests of successive years. But, so far as the Northern States are concerned, the enormous profits of this alleged wasteful cultivation have in the main been applied, not to personal consumption, but to permanent improvements,—not indeed to improvements of the land, but to what were still more needed in the situation, namely, improvements upon the land. The first-fruits of a virgin soil have been expended in forms which have vastly enhanced the productive power of the country. The land, doubtless, as one factor of that productive power, became temporarily less efficient than it would have been under a conservative European treatment; but the joint product of the three factors—land, labour, and capital—was for the time enormously increased. Under this regimen the fertility of the land of course in time necessarily declined, sooner or later according to the nature of the crops grown and to the degree of original strength in the soil. Resort was then had to new fields farther west. The granary of the continent moved first to western New York, thence into the Ohio valley, and then, again, to the banks of the Mississippi. The north and south line dividing the wheat product of the United States into two equal parts was in 1850 drawn along the 82d meridian. In 1860 that line was drawn

along the 85th, in 1870 along the 88th, in 1880 along the 89th. Meanwhile one portion of the inhabitants of the earlier settlements joined in the movement across the face of the continent. As the grain centre passed on to the west they followed it, too restless by character and habit to find pleasure in the work of stable communities. A second portion of the inhabitants became engaged in raising, upon limited areas, small crops, garden vegetables, and orchard fruits, and in producing butter, milk, poultry, and eggs, for the supply of the cities and manufacturing towns which had been built up out of the abundant profits of the primitive agriculture. Still another portion of the agricultural population gradually became occupied in the more careful and intense culture of the cereal crops upon the better lands, the less eligible fields being allowed to spring up in brush and wood. Deep ploughing and thorough drainage were resorted to; fertilizers were employed to bring up and to keep up the soil; and thus began the serious systematic agriculture of the older States. Something continued to be done in wheat, but not much. New York raised 13 million bushels in 1850; thirty years later she raised the same amount. Pennsylvania raised 15½ million bushels in 1850; in 1880 she raised 19½ million bushels. More is done in Indian corn (maize), that most prolific cereal, the backbone of American agriculture; still more is done relatively in buckwheat, barley, and rye. Pennsylvania, though the tenth State in wheat production, stands first in rye, second in buckwheat, third in oats. New York is only thirteenth in wheat, but first in buckwheat, second in barley, third in rye. We do not, however, reach the full significance of the situation until we account for the fourth portion of the former agricultural population, in noting how naturally and fortunately commercial and manufacturing cities spring up on the sites which have been prepared for them by the lavish expenditure of the enormous profits of a primitive agriculture upon permanently useful improvements of a constructive character. These towns are the gifts of agriculture.

The agricultural returns for 1880 showed a total of 4,008,907 Statistics farms, comprising 536,081,835 acres, of which 284,771,042 were of farms. improved and 251,310,793 unimproved. The improved lands were made up of 223,067,144 acres of tilled lands, including fallow or grasses in rotation, and 61,703,898 acres of permanent meadows, pastures, and orchards. The unimproved land comprises 190,255,744 acres of woodland and forest. The unimproved land in farms was, in 1860, 59.9 per cent. of the total land in farms; in 1870, 53.7; in 1880, 46.9. It will be seen that the farms of 1880 comprise little more than one-third the total area of the country. The remainder consists of large fertile tracts, which will, in the near future, be embraced in farms; of extensive districts, along the frontier, occupied by the grazing interest; of water surfaces, rivers, lakes, ponds, and swamps; of barren tracts along the shore, and of the area of innumerable rugged hills and vast mountain chains; and, lastly and chiefly, of the great arid plains beyond the 100th meridian.

The value of farms, including farm buildings, returned in 1880 was \$10,197,096,776; the value of farming implements and machinery, \$406,520,055; of live stock on farms, \$1,500,384,707. The live stock on farms comprised horses, 10,357,488; mules and asses, 1,812,808; working oxen, 993,841; milch cows, 12,443,120; other cattle, 22,488,550; sheep, exclusive of spring lambs, 35,192,074; swine, 47,681,700. The foregoing numbers relate only to live stock upon farms. The report of the special agent appointed in 1880 to canvass the grazing interest, outside the limits of defined farms, estimated the number of ranch and range animals as follows:—cattle, 3,750,000; sheep, 7,000,000; swine, 2,091,000.

The acreage and yield of the cereal grains reported in 1880 (crop Cereals. of 1879) were as follows:—wheat, 35,430,333 acres, 459,483,137 bushels; Indian corn, 62,368,504 acres, 1,754,591,676 bushels; oats, 16,144,593 acres, 407,858,999 bushels; barley, 1,997,727 acres, 43,997,495 bushels; rye, 1,842,233 acres, 19,831,595 bushels; buckwheat, 848,389 acres, 11,817,327 bushels.

Of wheat fourteen States produced over 10,000,000 bushels each, six States over 30,000,000. The chief producing States, with their respective crops in round millions of bushels, were Illinois, 51; Indiana, 47; Ohio, 46; Michigan, 35; Minnesota, 34; Iowa, 31; California, 29. 303 million bushels were produced in regions having a mean annual temperature of between 45° and 50° F., 51 millions between 40° and 45°, 59 millions between 55° and 60°. The general average yield per acre was 13 bushels.

Of Indian corn twenty States produced over 20 million bushels each, six over 100 millions. The chief producing States, with their respective crops in round millions of bushels, were Illinois, 326; Iowa, 275; Missouri, 202; Indiana, 115; Ohio, 112; Kansas, 106. 1300 million bushels were produced in regions having a mean annual temperature between 45° and 55°, 229 millions between 55° and 60°, 113 millions between 60° and 65°. The average yield per acre was 28 bushels.

Of oats ten States produced over 10 million bushels each; five produced over 30 millions. The chief producing States, with their respective crops in round millions of bushels, were Illinois, 63;

Iowa, 51; New York, 38; Pennsylvania, 34; Wisconsin, 33. The average yield per acre was 25 bushels. Of barley five States produced over 2 million bushels, as follows:—California, 12½; New York, 8; Wisconsin, 5; Iowa, 4; Minnesota, 3. The average yield per acre was 22 bushels. Of rye four States, namely, Pennsylvania, Illinois, New York, Wisconsin, produced between 3½ and 2 million bushels each. The average yield per acre was 11 bushels. Of buckwheat 70 per cent. of the crop was produced by the two States of New York (4½ millions) and Pennsylvania (3½ millions). The average per acre was 14 bushels.

Hay. The harvested hay crop, as reported in 1880, amounted to 35,150,711 tons from 30,631,054 acres. Thirteen States show more than one million acres mown, with a yield ranging from 0·385 ton per acre in Missouri to 1·554 tons in Minnesota. As we pass southward, the importance of the grass crop diminishes until we reach large and populous States in which but ten or twenty thousand acres or less are mown.

Dairy produce. The statistics of dairy products, taking those both of the home dairy and of the butter or cheese factory, as returned in 1880, show 806,672,071 lb of butter made, 243,157,850 lb of cheese, 217,922,090 gallons of milk sold otherwise than to cheese and butter factories.

Hops. The production of hops is mainly in two States,—New York, which in 1880 cultivated 39,072 acres in this crop, nearly all in four counties, and Wisconsin, which cultivated 4439 acres. The total area in hops was 46,800 acres, with a yield of 26,546,378 lb.

Potatoes. The potato crop comprised 169,458,539 bushels of Irish, grown mainly in Northern States, and 33,388,693 bushels of sweet, grown mainly in the South, although the profitable cultivation of this crop extends as far north as New Jersey.

Wool. The statistics of the wool crop in a census of the United States are necessarily defective, requiring to be supplemented by information from the outside. This is due to the great amount of wool obtained from the pelts of slaughtered sheep, to the large number of animals upon ranches and ranges along the frontier, beyond the limits of defined farms, and, thirdly, to the fact that in some regions, notably California and Texas, two clips are made each year. The gross figures for 1880, after making allowance on these accounts, were 240,681,751 lb.

Hemp and flax. The production of hemp in the census year was but 5025 tons; the products of the flax culture were stated at 7,170,951 bushels of seed, 421,098 tons of straw, 1,565,546 lb of the fibre. It is in cotton, however, that the United States make their chief contribution to the fibres of the commercial world. In 1879 5,755,359 bales were raised on 14,480,019 acres. The following table (XIV.) shows the distribution, geographically, of this most important crop:—

States.	Acres.	Bales.	States.	Acres.	Bales.
Alabama	2,330,086	699,654	Mississippi	2,106,215	963,111
Arkansas	1,042,976	608,256	Missouri	32,116	20,318
Florida	245,595	54,997	North Carolina	895,153	389,598
Georgia	2,617,138	814,441	South Carolina	1,364,249	522,548
Indian Territory	35,000	17,000	Tennessee	722,562	330,621
Kentucky	2,667	1,367	Texas	2,178,435	805,284
Louisiana	864,787	508,569	Virginia	45,040	19,595

Rice. The other characteristic crops of the Southern States are rice, tobacco, and sugar. Of rice there was raised in 1879 110,131,373 lb, of which South Carolina produced upwards of 52 millions, Louisiana and Georgia producing, in about equal proportion, nearly all the remainder. The area cultivated for the sugar-cane was 227,776 acres, from which the crop was 178,872 hhds. of sugar and 16,573,273 gallons of molasses. Of the sugar Louisiana produced 171,706 hhds.; Texas, 4951; Florida, 1273; Georgia, 601; South Carolina, 229; Alabama, 94; Mississippi, 18. In addition to the cane sugar of the far South, there were produced in the Middle and Northern States 12,792 lb of sorghum sugar and 28,444,202 gallons of sorghum molasses; while in the far North were produced 36,576,061 lb of maple sugar and 1,796,048 gallons of maple molasses. The chief sorghum-producing States are Missouri, Tennessee, Kentucky, Illinois, and Iowa. The chief maple-sugar States are Vermont, New York, Michigan, Ohio, Pennsylvania, and New Hampshire.

Sugar. The area sown in tobacco was 638,841 acres, the crop 472,661,157 lb. Fifteen States raised over 2 million pounds each; ten raised above 10 million each. The chief tobacco States were Kentucky, 171,120,784 lb; Virginia, 79,988,868; Pennsylvania, 36,943,272; Ohio, 34,735,285; Tennessee, 29,365,052; North Carolina, 26,986,218; Maryland, 26,082,147. The States next in order are Connecticut, Missouri, and Wisconsin.

Tobacco. In addition to the crops which have been mentioned, there were reported 102,272,135 barnyard fowls and 23,235,187 other fowls, producing 456,910,916 dozens of eggs; 25,743,208 lb of honey and 1,105,685 lb of wax; \$50,876,154 of orchard products, \$21,761,250 of market-garden products, \$95,774,735 of forest products; 29,480,106 lb of broom corn; 6,514,977 bushels of pease; and 3,075,050 bushels of beans.

Other agri-cultural produce. Since the census of 1880 the United States department of agriculture has published annually estimates of the successive

crops down to 1886. These estimates take the latest census figures for their basis, the percentages of increase or decrease being carefully computed with reference to the statements of several thousands of local reporters. The following table (XV.) represents the estimated annual production of the cereal crops for the six or seven years quoted:—

Grain.	Area Planted, in Acres.	Crop, in Bushels.	Average Yield, Bush. per Acre
Indian corn (1880-86)	68,435,634	1,639,655,363	24
Wheat (1880-86)	37,098,548	447,742,370	12·1
Oats (1880-86)	19,940,322	533,012,913	26·7
Rye (1880-85)	2,095,438	25,610,067	12·2
Barley (1880-85)	2,300,021	50,829,950	21·1
Buckwheat (1880-85)	858,313	11,089,007	12·9

No statistics are available regarding the tenure of non-agricultural Tenure land; but, of the 4,008,907 farms reported, 2,984,306 were cultivated by their owners, 322,357 by tenants for a fixed money rental, lands, 702,244 by tenants paying a share of the produce as rent. It thus appears that, of each 10,000 farms, 7444 were cultivated by owners, 804 were rented for fixed money payments, and 1752 were rented for a share of the produce.

The following table (XVI.) exhibits the distribution of the farms Size of 1880 according to size, with the further distinction of the kind of farms, tenure under which they were cultivated:—

	Cultivated by Owners.	Rented for Fixed Money Rental.	Rented for Shares of Produce.
Under 3 acres	2,601	875	876
3 and under 10 acres	85,456	22,904	26,529
10 and under 20 acres	122,411	41,822	90,816
20 and under 50 acres	460,486	97,389	223,689
50 and under 100 acres	804,522	69,663	158,625
100 and under 500 acres	1,416,618	84,645	194,720
500 and under 1000 acres	66,447	3,956	5,669
1000 acres and over	25,765	1,393	1,420

MANUFACTURES.

Down to the revolution, the very beginnings of manufactures were prohibited in the American colonies by the policy of the mother country. The history of American manufactures begins with the history of the United States. The natural resources of the country for the purposes of manufacture, whether in field, forest, or mine, were various and abundant in a high degree. The supply of coal was the marvel of the world, while the whole Atlantic coast was dotted over with immense water powers. Iron ores of the greatest variety, and often of high purity, were widely spread. The native woods were remarkable for their beauty, strength, and elasticity. A wealth of building stones, slates, and marbles underlay the surface, from New England to Tennessee and Alabama. Among fibres the soil had a high degree of adaptation to the production of those two which are the chief staples of textile manufacture. Indeed, in the cultivation of cotton this country has from the first been practically beyond the competition of any other.

Yet during the first years after 1790, although nearly every branch of mill and factory industry had been undertaken, the United States at the best attained only respectable standing among the manufacturing nations of the second rank. As yet the American people, as has been explained in a previous section, were employing their thoughts and energies, their resources, their capital, in reaping the first-fruits of a virgin soil. While capital applied to the soil in England was yielding 3 per cent., interest upon purely agricultural loans ranged from 8 to 15 per cent. in Indiana, Illinois, Wisconsin, and Iowa. While the English agricultural labourer was receiving from 9 to 13 shillings a week, the American farm hand was receiving from a dollar and a quarter to two dollars a day, according to the season of the year. At the same time hundreds of thousands of persons taking up farms in the new States, and paying such interest for capital and such wages for labour, saw their lands rise continuously in value through the growth of population and the intensification of settlement. In a word, it has been the competition of the farm with the shop that from 1790 down to the present time has hindered the development of manufactures.

No attempt was made, either at the first or second census, to obtain the statistics of manufactures. In 1810 Congress provided for a report of all manufacturing establishments; but it was found that this work had been so imperfectly done that no summary for the United States, or for any State, was possible. It is interesting to note that cotton cloth was set down at 80 cents a yard, pig iron at \$66 a ton, bar iron at \$151 a ton, while the average product of the grist mills was valued at 75 cents a bushel, and the average product of the saw mill at \$7·80 per 1000 feet. In 1820 and again in 1840 renewed attempts were made to obtain the statistics of manufactures, but the results were worthy of little consideration.

In 1850, among extensive changes introduced into the census system, provision was made on an ample scale for statistics of

manufactures; and it is accordingly from that date that official information on this subject may be said to begin. The results then obtained were as follows (Table XVII.):—

Number of establishments.....	123,025
Capital employed.....	\$533,245,351
Hands employed—	
Males.....	731,137
Females.....	225,922
Total.....	957,059
Wages paid.....	\$236,755,464
Cost of materials.....	\$555,123,822
Value of products.....	\$1,019,106,616

These statistics were intended to include the production, not of factories merely, but of mechanic shops of every kind. It was found, however, that the returns did not generally embrace the products of artisans working singly at their trades. The mining industries were included in the returns of manufactures.

Between 1850 and 1860 the capital employed had increased to \$1,009,855,715; the number of establishments was 140,433; the hands employed were—males 1,040,349, females 270,897, total 1,311,246; the wages paid were \$378,878,966; the cost of materials \$1,031,605,092; the value of products \$1,885,861,676.

The decade 1860–70 was marked by a stupendous advance in mechanical enterprises. The totals are (Table XVIII.):—

Number of establishments.....	252,148
Capital.....	\$2,118,208,769
Hands employed—	
Males above 16.....	1,615,595
Females above 16.....	323,770
Children and youths.....	114,628
Total.....	2,053,996
Wages paid.....	\$775,584,343
Cost of materials.....	\$2,488,427,242
Value of products.....	\$4,232,325,442

In addition to the foregoing statistics, it was ascertained that there were employed in manufactures 40,191 steam engines, of 1,215,711 aggregate horse-power, and 51,018 water wheels, of 1,130,431 aggregate horse-power.

In preparation of the tenth census (1880) the provisions for the collection of statistics of manufactures were greatly extended and improved. The totals are as follows (Table XIX.):—

Number of establishments.....	253,852
Capital.....	\$2,790,272,606
Hands employed—	
Males above 16.....	2,025,335
Females above 16.....	581,639
Children and youths.....	181,921
Total.....	2,788,895
Wages paid.....	\$947,953,795
Cost of materials.....	\$3,396,823,549
Value of products.....	\$5,369,579,131

The geographical distribution of the manufactures of 1880 is shown in the following table (XX.), the amounts being reduced to percentages:—

	Area.	Estab-lish-ments.	Capital In-vested.	Hands Em-ployed.	Wages Paid.	Product.
North Atlantic	5.6	44.87	61.94	62.23	64.33	59.64
South Atlantic	9.4	10.16	5.89	7.59	4.99	5.26
Northern Central.....	25.3	34.33	25.78	24.39	24.86	28.94
Southern Central.....	20.3	7.55	3.75	3.85	3.11	3.47
Western (Cordilleran) ..	39.4	3.09	2.64	1.94	2.71	2.69

The first ten cities, in order of the number of persons employed in manufactures, were New York, 227,352; Philadelphia, 185,527; Chicago, 79,414; Boston, 59,213; Baltimore, 56,338; Cincinnati, 54,517; Brooklyn, 47,587; St Louis, 41,823; Pittsburgh, 36,930; San Francisco, 28,442.

RAILROADS.

The following figures show the construction of railroads in the United States, by decades:—1830–40, 2265 miles; 1840–50, 5046; 1850–60, 20,110; 1860–70, 16,090; 1870–80, 41,454; 1880–85, 44,002,—giving a total of 128,967 miles.

Poor's *Railroad Manual* gives the cost of the railroads constructed down to 1885 as \$7,037,627,350, including equipment; capital stock, \$3,817,697,832; bonded debt, \$3,765,727,066; earnings for 1885—from passengers, \$200,883,911; from freight, \$519,690,992; from all sources, \$765,310,419; net earnings, \$266,488,993; interest paid on bonds, \$179,681,323; dividends paid on stock, \$77,672,105.

TELEGRAPHS.

The aggregate extent of telegraphic lines in the United States open for public business in 1887 exceeded 170,000 miles, besides railway, Government, private, and telephone lines, of which the extent is not known. By far the greater part of this business in the United States is in the hands of the Western Union Telegraph Company, the main features of whose operations, at certain successive dates, are shown in the following table (XXI.):—

	Miles of Line.	Miles of Wire.	No. of Offices.	No. of Messages Sent.	Receipts.
1867	46,270	85,291	2,565	5,379,282	\$6,568,925
1870	54,109	112,191	3,972	9,157,646	7,133,738
1875	72,833	179,496	6,565	17,153,710	9,564,575
1880	85,645	233,524	9,077	25,216,509	12,782,895
1885	147,500	463,283	14,184	42,096,583	17,708,834
1886	151,832	489,607	15,143	43,280,807	16,298,638
1887	156,814	524,641	15,658	47,394,530	17,191,910

The average toll per message was 36.3 cents in 1887. Since the construction of this table, the purchase of the Baltimore and Ohio Railroad telegraph lines has brought the mileage of the Western Union to about 162,000, with over 580,000 miles of wire.

POSTAL SERVICE.

The following table (XXII.), from the latest annual report of the postmaster-general, exhibits the growth of the postal services:—

Fiscal Years.	No. of Post-Offices.	Miles of Post Routes.	Revenue of Department.	Expenditure during the Year.
1790	75	1,875	\$37,935	\$32,140
1805	903	20,817	280,804	213,994
1810	2,300	36,406	551,684	496,969
1820	4,500	73,492	1,111,927	1,160,926
1830	8,450	115,176	1,850,583	1,932,708
1840	13,468	155,739	4,543,522	4,718,236
1850	18,417	178,672	5,490,985	5,212,953
1860	28,498	240,594	8,518,067	19,170,610
1870	28,492	231,232	19,772,221	23,998,838
1880	42,989	343,888	33,315,479	36,542,804
1885	51,252	365,251	42,560,843	50,046,235
1886	53,614	378,586	43,948,423	51,004,744

FOREIGN COMMERCE.

The full official statistics of the foreign commerce of the United States only begin with 1820. Prior to that date considerable statis-

TABLE XXIII.

	Domestic Merchandise.	Products of Domestic Agriculture.	Per cent. of Agr. Products.
1820	\$51,683,640	\$41,657,673	80.60
1830	58,524,878	48,095,184	82.18
1840	111,660,561	92,548,067	82.88
1850	184,900,233	108,605,713	80.50
1860	316,242,423	256,560,972	81.12
1870	455,208,341	361,188,483	79.34
1880	823,946,353	685,961,091	83.25

The table shows strikingly the constancy with which the exports of agricultural produce have maintained their share in the total exports during 60 years.

The following table (XXIV.) shows the value of all imports into the United States at intervals of five years from 1835 to 1880:—

	Value of Imports.		Value of Imports
1835	\$149,895,742	1860	\$362,160,254
1840	107,141,519	1865	248,555,652
1845	117,254,564	1870	462,377,587
1850	178,138,318	1875	595,861,248
1855	261,468,520	1880	760,989,046

In 1884, 1885, and 1886 respectively the total exports of merchandise amounted to \$740,513,609, \$742,189,755, and \$679,524,830, and the imports to \$667,697,693, \$577,527,329, and \$635,436,136. The same years the exports of gold and silver amounted to \$67,133,383, \$42,231,525, and \$72,463,410, and the imports to \$37,426,262, \$43,242,323, and \$38,593,656.

The following table (XXV.) gives the value, in round millions of dollars, of leading exports of domestic agriculture during each fifth year since 1860:—

	Cotton, Raw.	Bread Stuffs.	Leaf Tobacco.	Provisions, including Meats and Dairy Products.	Cattle, Sheep, and Hogs.
1860	192	24	16	17	1
1865	7	54	42	54	0
1870	227	72	21	31	1
1875	191	111	25	38	2
1880	212	288	16	132	15
1885	302	160	22	107	14

Table XXVI., p. 826, exhibits the value, in dollars, of the imports from, and exports to, each of the principal foreign countries in 1886.

The following are the eleven principal exporting cities, with the value of the goods going out through them in 1886, and percentage of total United States exports:—New York, 314 millions of dollars (49.26 per cent.); New Orleans, 83 (12.15); Boston, 54 (7.96); Baltimore, 36 (5.27); Philadelphia, 34 (4.97); San Francisco, 30 (4.45); Savannah, 20 (2.99); Charleston, 18 (2.6); Galveston, 17 (2.5);

TABLE XXVI.—Exports and Imports.

Exports from U.S. to each Country.	Per cent. of Total Exports.	Foreign Country.	Per cent. of Total Imports.	Imports into U.S. from each Country.
344,927,973	51.79	Great Britain and Ireland	24.28	154,254,054

2,695,488	.40	Venezuela91	5,731,621
1,110,545	.17	Uruguay78	4,925,948

Norfolk, 12 (1.71); Huron, Mich., 8 (1.22 per cent.). It thus appears that, of the aggregate exports from the United States, all but 7.92 per cent. (about 54 millions of dollars) go out from these eleven ports. By far the greater part of the exports of New Orleans, Savannah, Charleston, Galveston, and Norfolk consists of cotton. It is the shipment of this staple from Southern ports which increases the number of important exporting cities.

On the other hand, all but 8.48 per cent. of the imports, amounting to 54 millions, were in 1886 received at seven ports as follows:—New York, 419 millions of dollars (65.9 per cent. of imports into United States); Boston, 58 (9.2); San Francisco, 37 (5.8); Philadelphia, 37 (5.76); Baltimore, 12 (1.84); Chicago, 10 (1.6); New Orleans, 8 (1.28 per cent.).

The following table (XXVII.) exhibits the division of the imports of 1886 into two classes as free or dutiable, with the amount of duty collected on each of five principal groups of articles:—

Classes.	Value.		Duty.	Ad valorem rate on dutiable.	Per cent. of total duty.
	Free of duty.	Dutiable.			
(A) Articles of food and live animals...	\$83,752,303	\$112,433,925	\$61,004,744	54.26	32.42
(B) Articles in a crude condition which enter into the various processes of domestic industry.....	102,438,364	41,613,658	12,863,115	30.91	6.83
(C) Articles wholly or partially manufactured for use as materials in the manufacturing and mechanical arts....	10,089,156	67,855,317	20,115,152	29.64	10.68
(D) Articles manufactured ready for consumption	12,446,211	113,824,644	55,653,853	48.90	29.54
(E) Articles of voluntary use, luxuries, &c.....	2,204,725	78,030,511	33,682,533	49.58	20.53
Total.....	\$211,530,759	\$413,778,055	\$188,379,397	45.55	100.00

SHIPPING.

Shipbuilding was one of the earliest arts developed in the American colonies, and was prosecuted in the United States with the highest success until iron steamers began to drive out wooden sailing vessels. The following table (XXVIII.) exhibits the tonnage of the merchant marine of the country at ten-year intervals from 1790 to 1880:—

Date.	Sailing Vessels.	Steamers.	Total.
1790	478,377	...	478,377
1800	973,492	...	973,492
1810	1,424,783	...	1,424,783
1820	1,280,167	...	1,280,167
1830	1,127,304	64,472	1,191,776
1840	1,978,425	202,339	2,180,764
1850	3,009,507	525,947	3,535,454
1860	4,488,931	867,937	5,356,868
1870	3,171,412	1,075,095	4,246,507
1880	2,856,476	1,311,558	4,068,034

The decline in the American shipping interest since its maximum in 1860 is greater than would appear from the foregoing table, since the aggregate is kept up by the large lake, river, and coast fleets engaged in the coasting trade, which is by law confined to American vessels. The decline in registered tonnage, *i.e.*, that engaged in ocean traffic, since 1860 is shown by the following figures:—1860, 2,546,237 tons; 1865, 1,602,583; 1870, 1,516,800; 1875, 1,553,827; 1880, 1,352,810.

The decline above noted was due in the first instance to the war of 1861-65. About that time occurred the world-wide substitution of iron steamers for wooden sailing vessels or wooden steamers. In the new industry the American people have never achieved any marked success, while the law precludes the registering as American of vessels built abroad. Hence it is that the American merchant marine never recovered from the losses sustained between 1861 and 1865, and that the commerce of the country is carried on in an increasing proportion by foreign vessels. The latter fact is shown strikingly in the accompanying table (XXIX.) of exports and imports, in millions of dollars, carried in American and foreign vessels respectively.

In addition to the goods carried in vessels, about 57 million dollars' worth were in 1885 carried in cars and other land vehicles.

BANKING AND CURRENCY.

Mention has already been made (see above p. 775, § 272) of the issue of legal tender paper money, by the national Government, in 1862, and (p. 776, § 280) of the establishment of the national banking system of 1863. Specie payments were resumed on January 1, 1879. The following statement (Table XXX.), prepared at the office of the United States treasurer, exhibits the classification of the circulating medium of the United States on June 30, 1887, stating separately the amount of each class which is in the United States treasury, in the national banks, and in circulation:—

	In Treasury.	In National Banks.	In Circulation.	Total.
Gold coin and bullion.....	\$ 277,979,653.61	\$ 98,137,439.47	\$ 278,403,241.92	\$ 654,520,335
Gold certificates..	30,261,380	54,274,940	36,950,497	121,486,817
Silver certificates	3,425,183	3,535,479	138,582,538	145,543,150
Silver dollars and bullion.....	221,897,045.77	6,343,213	49,205,508.23	277,445,767
Subsidiary silver.	26,963,934.20	2,813,138.80	45,770,726	75,547,799
National bank notes	2,362,585	25,420,212	251,434,991	279,217,788
Legal tender notes	28,783,796.79	74,482,342	243,414,877.21	346,681,016
Certificates of deposit, currency	310,000	8,770,000	...	9,080,000
Fractional currency, estimated	2,366	564,266	6,377,284	6,943,916
Compound interest notes.....	192,880	192,880
One and two year notes of 1863...	65,605	65,605
Old demand notes	57,130	57,130
State bank circulation	98,697	98,697
Total.....	\$91,985,894.37	\$274,341,030.27	\$1,050,553,975.36	\$1,916,880,900

It needs to be stated that, in order to obtain the net circulating medium, the amounts given in the foregoing table should be reduced by the total amount of gold, silver, or currency certificates, inasmuch as the funds which these certificates represent are included in the aggregate. These deductions would leave the net amount \$1,640,770,933. To obtain the amount actually in the hands of the people, it would also be necessary to deduct the quantities of the other elements held by the treasury and by the national banks. The following table (XXXI.) exhibits the coinage of the United States by successive periods from 1793 to 1887:—

Fiscal Years.	Gold.	Silver.	Minor.	Total.
Average, 1793-1800	\$101,429	\$144,045	\$7,939	\$253,413
" 1801-1810	325,074	356,917	15,125	697,116
" 1811-1820	316,651	597,081	19,116	932,848
" 1821-1830	190,309	1,673,105	15,141	1,883,555
" 1831-1840	1,875,649	2,730,996	34,232	4,640,877
" 1841-1850	8,925,082	2,236,813	38,063	11,199,958
" 1851-1860	33,023,709	4,658,218	124,961	37,806,888
" 1861-1870	29,240,955	1,918,860	847,224	31,407,139
" 1871-1880	39,927,730	15,459,036	288,553	55,625,319
Actual, 1881	78,733,864	27,649,967	405,110	106,788,941
" 1882	89,418,448	27,733,389	644,758	117,841,595
" 1883	35,938,928	28,835,470	1,423,307	66,200,705
" 1884	27,932,824	28,773,388	1,174,710	57,880,922
" 1885	24,861,124	28,848,960	527,657	54,237,641
" 1886	34,077,380	30,022,348	17,378	64,117,106
" 1887	22,393,279	34,366,484	943,651	57,703,414

The following table (XXXII.) exhibits the resources and liabilities of the national banks, expressed in millions of dollars, on dates near the 1st of October of the years 1878, 1882, and 1886:—

Resources and Liabilities.	Oct. 1, 1878. 2053 Banks.	Oct. 3, 1882. 2269 Banks.	Oct. 7, 1886. 2852 Banks.
<i>Resources.</i>			
Loans	834.1	1243.2	1451.0
Bonds for Circulation	347.6	357.6	258.5
Other United States Bonds	94.7	37.4	32.4
Other Stocks, Bonds, &c.	36.9	66.2	81.8
Due from other Banks	138.9	198.9	241.4
Real Estate	40.7	46.5	54.1
Specie	30.7	102.9	156.4

INTERIOR POLITICAL ORGANIZATION.

The United States is, as has been seen, divided into thirty-eight States, eight Territories, and the District of Columbia. Each State and Territory is in turn divided into more or fewer counties, except only in the case of Louisiana, where primary divisions of the State are called parishes, the functions and relations of the parish being, however, substantially the same as those of the counties of the surrounding States. The number of organized counties in 1880 was 2444. The number of unorganized counties upon the frontier, laid out upon the map but not yet sufficiently filled by population to justify the completion of their political organization, was 161. The number of organized counties in the several States has a wide range,—from 3 in Delaware, 5 in Rhode Island, 8 in Connecticut, 10 in New Hampshire, to 114 in Missouri, 117 in Kentucky, 187 in Georgia, 160 in Texas.

Countries
and
town-
ships.

The political function of the county differs widely among the several States. In general, it may be said that in the north-east, where the counties are few, the county bears but a slight relation to the affairs of the people. It is the unit of real estate record. Courts are, indeed, held at the county seat, but judges who have equal jurisdiction in other counties there administer laws which run equally over the entire State. The commissioners of the county have authority over certain main roads. This said, all is said. The county means almost nothing to the citizen. It is the so-called "town" (*i.e.*, township) which in this region has the power to deal directly with schools, which administers poor relief, which builds and keeps in repair most of the roads and bridges, which has the charge of the public peace, which holds nearly all the authority which, by the laws of the State, is vested anywhere for promoting the general welfare. These "small elemental republics," as President Jefferson called them, absorb a large part of the political interest of the people; their names are the objects of much affection and pride to their inhabitants; their boundaries can only be changed by the legislature of the State, and this is only done from important considerations of public convenience, and that too, generally, with their own consent.

On the other hand, in the South and extreme West, where the number of counties is very large, the county exercises or controls the exercise of nearly all the powers, excepting in the case of cities and incorporated towns, which by the laws of the State are conceded to any political agency. The geographical subdivisions

of the county become here of comparatively little, sometimes of very little, importance. In some States their boundaries may be changed by county judges or county commissioners, for trivial, perhaps for purely temporary reasons. In some States these subdivisions of the county are little more than voting districts. In other States they are convenient units of political administration.

Midway, both geographically and politically, between the two groups which have been indicated, are many States, originally settled largely by emigrants from New England and New York, in which the political powers conceded by the constitution and laws of the several States are divided, not very unequally, between the county and the township. The county, as a whole, here takes charge of a very much larger range of public interest than in the north-east. On the other hand, the township has much of the political power and dignity which belongs to the New England town. The aggregate number of such subdivisions of counties in all the States and Territories, so far as ascertained, is 26,682.

Law and usage differ very widely among the American States Incorpo- regarding the incorporation of cities, towns, and villages. In rated Massachusetts no town is incorporated of less than 10,000 towns inhabitants. In the West and South, villages of two and three and hundred inhabitants are sometimes incorporated. In some cases, cities, when a township acquires sufficient population it is made a city, embracing the entire area, including perhaps a large rural region. In other cases, only the closely occupied district is embraced within the municipal limits, and the township continues to maintain its political existence. In the latter class of cases it sometimes happens that the inhabitants of the borough or village are members of the township for certain purposes, though not for others; at other times the township and the borough, or incorporated village, become as distinct as if they were two townships or two boroughs. The number of incorporated cities in the United States is 969, of incorporated towns and villages 4,613, of boroughs 532. In two cases, New York and Philadelphia, a city makes up an entire county. In two cases, St Louis and Baltimore, a large city forms no part of a county. The District of Columbia has no county organization, while the city of Washington, contained therein, has no municipal charter.

TAXATION.

The taxing powers within the United States are as follows:—

A. The national Government, whose revenue powers are only limited by—(a) the provision of the constitution which prohibits all duties on exports, and (b) the provision that all direct taxes must be levied in proportion to population,—a provision which deprives direct taxes of nearly all their efficiency for revenue purposes;

B. The several States, whose revenue powers are only limited by—(a) restrictions in their respective constitutions, and (b) the general principle that those powers must not be exercised in such a way as to contravene laws of the United States, or to destroy sources of the national revenue, although a State may prohibit within its borders the sale of liquors, from which the United States treasury derives a considerable part of its receipts.

C. Within each State, powers of taxation, to a determinate or to an indeterminate extent, as the case may be, are by the constitution and laws of the State conferred, almost always for strictly defined purposes, (1) upon counties, (2) upon cities, boroughs, and incorporated villages, and (3) in nearly all the States, though in widely varying degrees, upon the primary geographical divisions of counties, such as the "town" of New England and the "township" of the Middle and Western States.

The revenues of the several States, and of the counties, cities, townships, &c., are generally derived from direct taxes upon property, real and personal, although in some States licences and fees and taxes on franchises and incomes bear a not inconsiderable part. The revenues of the United States are, and have historically been, mainly derived from two species of indirect taxes, *viz.*, customs duties on imports and excise duties on articles as produced or consumed within the country, notably liquors and tobacco. At three several periods, *viz.*, 1800–02, 1814–17, and 1863–71, direct taxes have contributed considerable amounts to the national revenue. At times the proceeds of the sales of public lands have formed an important element of the receipts of the general Government; but in the main it has been the accepted policy to sell lands to actual settlers at rates so low as to be inconsistent with the object of revenue. Indeed, under the homestead law, large portions of the public domain have been given away to settlers, while even larger amounts have been alienated in aid of schools, public improvements, &c. A detailed table, prepared by Prof. A. B. Hart, shows that up to 1884 192,584,116 acres had been sold, 162,230,099 had been granted to States and corporations for internal improvements, and 325,901,100 had been granted (167,483,506 to individuals and 158,417,594 to States) for other purposes,—making a total of 680,715,315 acres.

At the tenth census (1880) an effort was made to obtain statistics covering the amounts raised, in one year, under all the taxing powers authorized and exercised in the United States. The diffi-

culty lay wholly in obtaining the facts relating to revenues collected by counties and by taxing agencies below the county. The aggregate results, as ascertained for 1879, were as follows (Table XXXIV.):—

Receipts into the U.S. treasury (ordinary revenue).....	\$273,322,137
Receipts into the State (or Territorial) treasuries.....	52,019,955
Receipts into the county treasuries.....	69,606,571
Receipts into the treasuries of cities, boroughs, or incorporated villages, and of townships and other subdivisions of counties.....	191,081,951

Total..... \$584,980,614

Receipts The aggregate receipts into the United States treasury, beginning in 1791, have been (in millions of dollars) as follows:—from customs, 5642; from internal revenue, 3449; from direct taxes, 28; from public lands, 241; from bank dividends, 10; miscellaneous, 568; total, 9938. The net ordinary expenditures of the United States Government from 1791 to 1886 have been as follows (in millions of dollars):—war, 4563; navy, 1106; Indians, 230; pensions, 900; miscellaneous, 1938; total, 8737. The foregoing is exclusive of payments on account of the principal or interest of the public debt.

in 1886.

The net ordinary receipts into the treasury for 1886 (the fiscal year ends June 30) were as follows:—from customs, \$192,905,023; from internal revenue, \$116,805,937; from direct taxes, \$108,240; from public lands, \$5,630,999; miscellaneous, \$20,989,528; total, \$336,439,727. Of the receipts from internal revenue in 1886 \$69,000,000 in round numbers were from spirits, \$20,000,000 from fermented liquors, 28,000,000 from tobacco. The net ordinary expenditures for 1886 were as follows:—war, \$34,324,153; navy, \$13,907,888; Indians, \$6,099,158; pensions, \$63,404,864; miscellaneous, 74,166,929; total, \$191,902,992. The foregoing statement is exclusive of payments on account of principal or interest of the public debt.

PUBLIC DEBT.

The Government set out, in 1790, with a revolutionary debt of about 75 millions of dollars. This debt continued without important change until 1806, when a reduction began, continuing until 1812, when the debt was about 45 millions. The then ensuing war with England carried the debt up to 127 millions in 1816. This was reduced to 96 millions in 1819, to 84 millions in 1825, and to 24 millions in 1832, and in the three years following was extinguished. The crisis of 1837, and the financial difficulties ensuing, created indebtedness, fluctuating in amount, which at the beginning of the war with Mexico was about 16 millions. At the conclusion of peace the debt had risen to 63 millions, near which point it remained until about 1852, from which time successive reductions brought it down to 28 millions in 1857. The financial crisis of that year caused an increase, which continued until the imminence of the civil war, when it rose from 65 millions in 1860 to 91 millions in 1861, to 514 in 1862, to 1120 in 1863, to 1816 in 1864, to 2881 in June and its maximum (2845 millions) in August 1865.

Of the outstanding principal of the debt in 1886, 158 millions bore interest at 3 per cent., 738 millions at 4 per cent., 250 millions at 4½ per cent., making the interest-bearing debt 1146 millions. The debt bearing no interest amounted to 629 millions, making the aggregate 1775 millions. The cash in the treasury on the 1st of July of that year reached 493 millions, leaving the total debt, less cash in the treasury, 1282 millions. The annual interest-charge was at this date 45½ millions.

At the tenth census (1880) an effort was made to ascertain the indebtedness of all States, Territories, counties, cities, towns, townships, &c., with the following result (in millions of dollars):—total funded debt, 1118; floating debt, 84; gross debt, 1202; sinking fund, 145; net debt, 1057. The total net debt was made up as follows (in millions of dollars):—debts of States and Territories, 234; debts of counties, 124; debts of townships, 32; debts of school districts, 17; debts of cities and towns, 649.

PENSIONS.

The number of pensioners on the rolls, June 30, 1887, with the amounts due the several classes, at existing rates per year, will be found in the following table (XXXV.):—

		Number.	Amount.
Army.....	Invalids.....	294,445	\$36,063,345
	Widows, &c.....	85,010	13,313,455
Navy.....	Invalids.....	3,281	429,288
	Widows, &c.....	1,973	405,288
War of 1812.....	Survivors.....	1,069	103,392
	Widows, &c.....	11,831	1,703,664
War with Mexico.....	Survivors.....	7,503	720,288
	Widows, &c.....	895	85,920
		406,007	\$52,824,640

CIVIL SERVICE.

It is impossible to make even an approximation to the number of persons in the civil service within the United States, including the officers of States, counties, cities, towns, &c. There is no com-

plete and exact statement available even as to those who are in the civil service of the national Government. An attempt has been made, for the present purpose, to reach an approximation to that number. This has been done by counting the names on 1200 pages of the blue-book of 1885, under the several heads there mentioned. Such a process involves a liability to minor errors, in addition to whatever duplications or omissions may occur in the printed lists. The results are offered merely as an approximation to facts. Legislative branch, 427; executive branch, 114,852; judicial branch, 2876; total, 118,155. The executive branch includes—executive, 22; state department, 467; war department, 9050; navy department, 1637; interior department, 6115; treasury department, 14,505; post-office department, 79,110; department of agriculture, 203; national museum, 154; Fish Commission, 118; Government printing office, 2238; government of the District of Columbia, 1200; miscellaneous, 33.

ARMY.

The following table (XXXVI.) exhibits the personnel of the army on January 1, 1887:—

	Officers.	Enlisted Men.	Professors.	Cadets.
General officers.....	10
Adjutant-general's department....	17
Inspector-general's department....	7
Judge-advocate-general's dept....	8
Quartermaster's department.....	61
Subsistence department.....	26
Medical department.....	195	140
Pay department.....	48
Corps of engineers.....	109	450
Ordnance department.....	59	400
Signal corps.....	17	470
Post chaplains.....	30
Ten regiments of cavalry.....	432	7,970
Five regiments of artillery.....	280	2,650
Twenty-five regiments of infantry	877	12,625
Military academy.....	7	244
Non-commissioned staff un-	...	300
attached to regiments.....
Enlisted men unattached to regi-	...	265
ments.....	...	200
Indian scouts.....
General service clerks and mes-	...	170
sengers.....
Total regular army.....	2176	25,640
Organized and equipped militia,	6535	75,175
1885.....

NAVY.

The following table (XXXVII.) exhibits the personnel of the navy on January 1, 1887:—

Commissioned officers, line.....	750
Commissioned officers, staff—	
Medical department.....	163
Pay department.....	111
Engineers.....	228
Other staff officers.....	64
Cadets.....	243
Non-commissioned officers.....	185
Enlisted men and boys.....	8250

Marine Corps.

Commissioned officers.....	73
Enlisted men.....	1500

The following table (XXXVIII.) exhibits the number of vessels constituting the navy of the United States, according to class and condition, on January 1, 1887:—

	In Commission.	In Ordinary.	Building or Repairing.
First-rate armoured.....	1	...	2
Second-rate unarmoured.....	10
Third-rate armoured.....	1	12	5
Third-rate unarmoured.....	17	...	5
Fourth-rate armoured.....	...	1	...
Fourth-rate unarmoured.....	4	...	1
Tugs.....	11	1	...
Sailing vessels.....	12
Total.....	56	14	13

Ten are unserviceable; 3 of these are used as receiving ships, the others condemned and authorized to be sold.

EDUCATION.

The institution, control, and maintenance of public schools are in the hands of the several States, although the United States Government has made liberal grants of lands, in aid of primary instruction, to the States formed out of the public domain, and also for the endowment of colleges of agriculture and the mechanic arts, to all the States.

The following table (XXXIX.) presents the leading features of the public school statistics at four dates between 1876 and 1886:—

TABLE XLI.—*Religious Denominations.*

	Enrolment.	Average Daily Attendance.	Number of Teachers.	Public School Expenditure.
1876	8,363,738	4,066,848	249,283	\$84,005,333
1880	9,781,521	5,805,342	282,644	80,032,838
1885	11,169,923	6,900,625	319,549	110,384,657
1886	11,435,297	7,279,616	323,066	111,304,927

The so-called public schools, although differing widely as to efficiency between new States and old States, between rich States and poor States, all conform closely to a traditional type, except so far as differences arise according as schools are in sparsely or in densely settled districts through the opportunity for grading the pupils which exists in the latter case. As regards, however, schools giving instruction higher than or other than that given in the ordinary public school, the greatest and most confusing differences exist as to designation, organization, and schemes of instruction.

The following table (XLI.) presents the results of the compilations of the statistics of schools of the various classes by the United States Bureau of Education:—

	Schools.	Teachers.	Pupils.
Normal schools.....	153	1394	40,325
Commercial and business colleges.....	239	1040	47,176
Kindergartens.....	417	945	21,640
Institutions for secondary instruction.....	1440	7566	151,050
Preparatory schools.....	197	1434	21,031
Institutions for superior instruction of women.....	204	2123	27,143
Universities and colleges.....	345	4720	67,642
Schools of science.....	90	974	10,532
Schools of theology.....	142	803	6,344
Schools of law.....	49	283	3,054
Schools of medicine, of dentistry, and of pharmacy.....	175	2829	16,407
Training schools for nurses.....	29	139	837
Institutions for deaf and dumb.....	61	596	7,411
Institutions for the blind.....	29	623	2,412
Schools for feeble-minded children.....	16	636	2,942
Reform schools.....	43	877	9,213
Industrial and manual training schools.....	63	582	13,300

RELIGION.

The census has since 1850 attempted to obtain the number of church edifices, with the aggregate number of sittings, belonging to each principal sect or denomination. The results have not been highly satisfactory, either as to accuracy or as to classification. At the census of 1880 the attempt to collect the statistics of churches proved an almost total failure. It seems best, therefore, to adopt, for the present purpose, the figures (Table XLI.) presented by the representatives of the various denominations, as they have been revised and digested by a competent authority, the Rev. Dr W. H. Dupuy, only adding the remark that no statement of this kind can be made to meet the views of all persons interested. The statement of Dr Dupuy does not include the Roman Catholic Church, whose authorities claim from six and a half to seven millions of adherents.

UNIVERSALIST CHURCH, a religious body in the United States of America, especially in the New England States, which has for its distinguishing tenet the doctrine of the final salvation of all souls from sin through Christ. The pioneers of Universalism in America were Dr George De Benneville, who taught from 1741 principally in Pennsylvania; Dr Charles Chauncy, of the First Church, Boston (notably in *The Salvation of All Men*, published in 1784); Dr Joseph Huntington, of Coventry, Conn. (whose *Calvinism Improved* was published after his death in 1796); John Murray, Elhanan Winchester, Caleb Rich, and, very specially, Hosea Ballou. Murray is, however, regarded as "the father of Universalism in America." In 1750 James Rely had avowed himself a Universalist, basing his belief on a theory quite peculiar; Murray, who had preached as a Methodist in England and Ireland, was Rely's most distinguished convert. In 1770 he came to America, and, under circumstances so strange that most Universalists regard them as providential, overcoming a deep reluctance, he preached at Good Luck, New Jersey, and organized a society, "The Independent Christian Church," at Gloucester, Massachusetts. Hosea Ballou—a convert from the Calvinist Baptists—took up the cause in 1790, and published the work that is regarded by Universalists as

epoch-making, *A Treatise on Atonement*. The number of ministers increased, and societies were formed. These in due time became the constituents of larger organizations, till a "New England convention" saw occasion, in 1803, to adopt a "profession of faith," which in three short articles avowed belief in the Bible as making known in a Divine revelation the nature of God, the mission of Christ, the final holiness of all souls, and the necessity of good works. In 1866 a general convention, composed of delegates from the State conventions, was incorporated. It has jurisdiction throughout the United States and Canada. It has a "Murray fund" of about \$135,000. Under the auspices of the Universalist Church are the "woman's centenary association," the "Universalist historical society," several organized charities, four colleges, three theological schools, and five academies,—the total value of the schools, including endowments, being hardly less than 3 million dollars. It publishes eight periodicals. The *Year Book* for 1887 gives the following summary:—1 general convention; 22 State conventions; 945 parishes, 38,429 families; 696 churches, 35,550 members; 634 Sunday schools, 51,871 members; 789 church edifices; value above indebtedness, \$7,493,927; 673 clergymen in fellowship and 120 licensed lay preachers.

U N I V E R S I T I E S¹

Original meaning of the term "university."

Its limitation in mediæval times.

THE mediæval Latin term *universitas* (from which the English word "university" is derived) was originally employed to denote any community or corporation regarded under its collective aspect. When used in its modern sense, as denoting a body devoted to learning and education, it required the addition of other words in order to complete the definition,—the most frequent form of expression being "*universitas magistrorum et scholarium*" (or "*discipulorum*"). In the course of time, probably towards the latter part of the 14th century, the term began to be used by itself, with the exclusive meaning of a community of teachers and scholars whose corporate existence had been recognized and sanctioned by civil or ecclesiastical authority or by both. But the more ancient and customary designation of the university in mediæval times (regarded as a place of instruction) was "*studium generale*" (or sometimes "*studium*" alone), a term implying a centre of instruction for all.² The expressions "*universitas studii*" and "*universitatis collegium*" are also occasionally to be met with in official documents.

It is necessary, however, to bear in mind, on the one hand, that a university often had a vigorous virtual existence long before it obtained that legal recognition which entitled it, technically, to take rank as a "*studium generale*," and, on the other hand, that hostels, halls, and colleges, together with complete courses in all the recognized branches of learning, were by no means necessarily involved in the earliest conception of a university. The university, in its earliest stage of development, appears to have been simply a scholastic guild,—a spontaneous combination, that is to say, of teachers or scholars, or of both combined, and formed probably on the analogy of the trades guilds, and the guilds of aliens in foreign cities, which, in the course of the 13th and 14th centuries, are to be found springing up in most of the great European centres. The design of these organizations, in the first instance, was

little more than that of securing mutual protection,—for the craftsman, in the pursuit of his special calling,—for the alien, as lacking the rights and privileges inherited by the citizen. And so the university, composed as it was to a great extent of students from foreign countries, was a combination formed for the protection of its members from the extortion of the townsmen and the other annoyances incident in mediæval times to residence in a foreign state. It was a first stage of development in connexion with these primary organizations, when the chancellor of the cathedral, or some other authority, began, as we shall shortly see, to confer on their masters the right of teaching at any similar centre that either already existed or might afterwards be formed throughout Europe,—"*facultas ubique docendi*." It was a still further development when it began to be recognized that, without a licence from either pope, emperor, or king, no "*studium generale*" could be formed possessing this right of conferring degrees, which originally meant nothing more than licences to teach.

In order, however, clearly to understand the conditions under which the earliest universities came into existence, it is necessary to take account, not only of their organization, but also of their studies, and to recognize the main influences which, from the 6th to the 12th century, served to modify both the theory and the practice of education. In the former century, the schools of the Roman empire, which had down to that time kept alive the traditions of pagan education, had been almost entirely swept away by the barbaric invasions. The latter century marks the period when the institutions which supplied their place—the episcopal schools attached to the cathedrals and the monastic schools—attained to their highest degree of influence and reputation. Between these and the schools of the empire there existed an essential difference, in that the theory of education by which they were pervaded was in complete contrast to the simply secular theory of the schools of paganism. The cathedral school taught only what was supposed to be necessary for the education of the priest; the monastic school taught only what was supposed to be in harmony with the aims of the monk. But between the pagan system and the Christian system by which it had been superseded there yet existed some-

¹ It is the design of the present article to exhibit the universities in their historical development, each being brought under notice, as far as practicable, in the order of its original foundation. In the alphabetical enumeration in the table at the end, the date of foundation thus serves to indicate approximately the place where any university is first referred to.

² Denifle, *Die Universitäten des Mittelalters*, i. 39.

thing that was common to both: the latter, even in the narrow and meagre instruction which it imparted, could not altogether dispense with the ancient text-books, simply because there were no others in existence. Certain treatises of Aristotle, of Porphyry, of Martianus Capella, and of Boetius continued consequently to be used and studied; and in the slender outlines of pagan learning thus still kept in view, and in the exposition which they necessitated, we recognize the main cause which prevented the thought and literature of classic antiquity from falling altogether into oblivion.

Revival
in time
of Charles
the Great.

Under the rule of the Merovingian dynasty even these scanty traditions of learning declined throughout the Frankish dominions; but in England the designs of Gregory the Great, as carried out by Theodorus, Bede, and Alcuin, resulted in a great revival of education and letters. The influence of this revival extended in the 8th and 9th centuries to Frankland, where Charles the Great, advised and aided by Alcuin, effected a memorable reformation, which included both the monastic and the cathedral schools; while the school attached to the imperial court, known as the Palace School, also became a famous centre of learned intercourse and instruction.

Its con-
nexion
with uni-
versity of
Paris
doubtful.

But the activity thus generated, and the interest in learning which it served for a time to diffuse, well nigh died out amid the anarchy which characterizes the 10th century in Latin Christendom, and it is at least questionable whether any real connexion can be shown to have existed between this earlier revival and that remarkable movement in which the university of Paris had its origin. On the whole, however, a clearly traced, although imperfectly continuous, succession of distinguished teachers has inclined the majority of those who have studied this obscure period to conclude that a certain tradition of learning, handed down from the famous school over which Alcuin presided at the great abbey of St Martin at Tours, continued to survive, and became the nucleus of the teaching in which the university took its rise. But, in order adequately to explain the remarkable development and novel character which that teaching assumed in the course of the 12th and 13th centuries, it is necessary to take account of the operation of certain more general causes to which the origin of the great majority of the earlier universities may in common unhesitatingly be referred. These causes are—(1) the introduction of new subjects of study, as embodied in a new or revived literature; (2) the adoption of new methods of teaching which were rendered necessary by the new studies; (3) the growing tendency to organization which accompanied the development and consolidation of the European nationalities.

General
causes of
formation
of first
universi-
ties.

That the earlier universities took their rise to a great extent in endeavours to obtain and provide instruction of a kind beyond the range of the monastic and cathedral schools appears to be very generally admitted, and this general fact has its value in assisting us to arrive at a conclusion with respect to the origin of the first European university,—that of Salerno in Italy, which became known as a school of medicine as early as the 9th century. The circumstances of its rise are extremely obscure, and whether it was monastic or secular in its origin has been much disputed. One writer¹ derives its origin from an independent tradition of classical learning which continued to exist in Italy down to the 10th century. Another writer² maintains that it had its commencement in the teaching at the famous Benedictine monastery of Monte Cassino, where the study of medicine was undoubtedly pursued. But various facts may be urged in contraven-

Rise of
uni-
versity of
Salerno.

tion of such a theory. The school at Salerno, so far as its history can be traced, appears to have been entirely a secular community; it was distinguished also by its catholic spirit, and, at a time when Jews were the object of religious persecution throughout Europe, members of this nationality were to be found both as teachers and learners at Salerno. Situated, moreover, as it was on the sea-coast, its communication with the neighbouring island of Sicily was easy and frequent; and it would accordingly seem far more probable that it was owing to the new knowledge gained from the Saracens, after their occupation of that island, that Salerno acquired its reputation. It was by a band of these invaders that Bertharius, abbot of Monte Cassino, and the author of certain medical treatises, was massacred along with his monks in the year 883. The Saracens were famed for their medical skill, and, by their translations of Galen and Hippocrates, did much to advance the study; and, according to Jourdain,³ there were translations from the Arabic into Latin long before the time of Constantine the African, but these versions have perished. In the course of the 11th century, under the teaching of Constantine the African (d. 1087), the celebrity of Salerno became diffused all over Europe. Ordericus Vitalis, who wrote in the first half of the 12th century, speaks of it as then long famous. In 1231 it was constituted by the emperor Frederick II. the only school of medicine in the kingdom of Naples.

It was at a considerable interval after the rise of the school at Salerno, about the year 1113, that Irnerius commenced at Bologna his lectures on the civil law. This instruction, again, was of a kind which the monastic and cathedral schools could not supply, and it also met a new and pressing want. The states of Lombardy were at this time rising rapidly in population and in wealth; and the greater complexity of their political relations, their increasing manufactures and commerce, called for a more definite application of the principles embodied in the codes that had been handed down by Theodosius and Justinian. But the distinctly secular character of this new study, and its intimate connexion with the claims and prerogatives of the Western emperor, aroused at first the susceptibilities of the Roman see, and for a time Bologna and its civilians were regarded by the church with distrust and even with alarm. These sentiments were not, however, of long duration. In the year 1151 the appearance of the *Decretum* of Gratian, largely compiled from spurious documents, invested the studies of the canonist with fresh importance; and numerous decrees of past and almost forgotten pontiffs now claimed to take their stand side by side with the enactments contained in the *Corpus Juris Civilis*. They constituted, in fact, the main basis of those new pretensions asserted with so much success by the popedom in the course of the 12th and 13th centuries. It was necessary, accordingly, that the *Decretum* should be known and studied beyond the walls of the monastery or the episcopal palace, and that its pages should receive authoritative exposition at some common centre of instruction. Such a centre was to be found in Bologna. The needs of the secular student and of the ecclesiastical student were thus brought for a time into accord, and from the days of Irnerius down to the close of the 13th century we have satisfactory evidence that Bologna was generally recognized as the chief school both of the civil and the canon law.⁴ It has indeed been asserted that university degrees were instituted there as early as the pontificate of Eugenius III. (1145–53), but the statement rests on no good authority, and is in every way improbable. There is, however, another tradition which is in better harmony

Barbarossa grants privileges to foreign students at Bologna.

with the known facts. When Barbarossa marched his forces into Italy on his memorable expedition of 1155, and reasserted those imperial claims which had so long lain dormant, the professors of the civil law and their scholars, but more especially the foreign students, gathered round the Western representative of the Roman Cæsars, and besought his intervention in their favour in their relations with the citizens of Bologna. A large proportion of the students were probably from Germany; and it did not escape Frederick's penetration that the civilian might prove an invaluable ally in the assertion of his imperial pretensions. He received the suppliants graciously, and, finding that their grievances were real, especially against the landlords in whose houses they were domiciled, he granted the foreign students substantial protection, by conferring on them certain special immunities and privileges (November 1158).¹ These privileges were embodied in the celebrated *Authentica, Habita*, in the *Corpus Juris Civilis* of the empire (bk. iv. tit. 13), and were eventually extended so as to include all the other universities of Italy. In them we may discern the precedent for that state protection of the university which, however essential at one time for the security and freedom of the teacher and the taught, has been far from proving an unmixed benefit,—the influence which the civil power has thus been able to exert being too often wielded for the suppression of that very liberty of thought and inquiry from which the earlier universities derived in no small measure their importance and their fame.

The "universities" at Bologna.

But, though there was a flourishing school of study, it is to be observed that Bologna did not possess a university so early as 1158. Its first university was not constituted until the close of the 12th century. The "universities" at Bologna were, as Denifle has shown, really student guilds, formed under influences quite distinct from the protecting clauses of the *Authentica*, and suggested, as already noted, by the precedent of those foreign guilds which, in the course of the 12th century, began to rise throughout western Europe. They had their origin in the absolute necessity, under which residents in a foreign city found themselves, of obtaining by combination that protection and those rights which they could not claim as citizens. These societies were modelled, Denifle considers, not on the trade guilds which rose in Bologna in the 13th century, but on the Teutonic guilds which arose nearly a century earlier in north-western Europe, being essentially "spontaneous confederations of aliens on a foreign soil." Originally, they did not include the native student element.

Democratic character of these communities.

The power resulting from this principle of combination, when superadded to the privileges conferred by Barbarossa, gave to the students of Bologna a superiority of which they were not slow to avail themselves. Under the leadership of their rector, they extorted from the citizens concessions which raised them from the condition of an oppressed to that of a specially privileged class. The same principle, when put in force against the professors, reduced the latter to a position of humble deference to the very body whom they were called upon to instruct, and imparted to the entire university that essentially democratic character by which it was afterwards distinguished. It is not surprising that such advantages should have led to an imitation and extension of the principle by which they were obtained. Denifle considers that the "universities" at Bologna were at one time certainly more than four in

number, and we know that the Italian students alone were subdivided into two,—the Tuscans and the Lombards. In the centres formed by secession from the parent body a like subdivision took place. At Vercelli there were four "universitates," composed respectively of Italians, English, Provençals, and Germans; at Padua there were similar divisions into Italians, French (*i.e.*, *Francigenæ*, comprising both English and Normans), Provençals (including Spaniards and Catalans). When accordingly we learn from Odofred that in the time of the eminent jurist Azo, who lectured at Bologna about 1200, the number of the students there amounted to some ten thousand, of whom the majority were foreigners, it seems reasonable to conclude that the number of these confederations of students ("societates scholarium") at Bologna was yet greater. It is certain that they were not formed simultaneously, but, similarly to the free guilds, one after the other,—the last in order being that of the Tuscans, which was composed of students from Tuscany, the Campagna, and Rome. Nor are we, again, to look upon them as in any way the outcome of those democratic principles which found favour in Bologna, but rather as originating in the traditional home associations of the foreign students, fostered, however, by the peculiar conditions of their university life. As the Tuscan division (the one least in sympathy, in most respects, with Teutonic institutions) was the last formed, so, Denifle conjectures, the German "university" may have introduced the conception which was successively adopted by the other nationalities.

In marked resemblance to the guilds, these confederations were presided over by a common head,—the "rector scholarium," an obvious imitation of the "rector societatum" or "artium" of the guild, but to be carefully distinguished from the "rector scholarum," or director of the studies, with whose function the former officer had, at this time, nothing in common. Like the guilds, again, the different nations were represented by their "consiliarii," a deliberative assembly with whom the rector habitually took counsel.

While recognizing the essentially democratic character of the constitution of these communities, it is to be remembered that the students, unlike the majority at Paris and later universities, were mostly at this time of mature years. As the civil law and the canon law were at first the only branches of study, the class whom they attracted were often men already filling office in some department of the church or state,—archdeacons, the heads of schools, canons of cathedrals, and like functionaries forming a considerable element in the aggregate. It has been observed, indeed, that the permission accorded them by Frederick I. of choosing, in all cases of dispute, their own tribunal, thus constituting them, to a great extent, *sui juris*, seems to presuppose a certain maturity of judgment among those on whom this discretionary power was bestowed.

With the middle of the 13th century, these various confederations became blended, for the first time, into one or other of the two great divisions already referred to,—those of the Ultramontani and the Citramontani, Johannes de Varanis being rector of the former and Pantaleon de Venetiis of the latter. Innocent IV., in according his sanction to the new statutes of the university in 1253, refers to them as drawn up by the "rectores et universitas scholarium Bononiensium." With the commencement of the 16th century, the two corporations were combined under one rector.

About the year 1200 were formed the two faculties of medicine and philosophy (or the arts²), the former being instituted

¹ See Savigny, *Gesch. d. röm. Rechts*, iii. 152, 491–492. See also Giesebrecht, *Gesch. d. Kaiserzeit* (ed. 1880), v. 51–52. The story is preserved in a recently discovered metrical composition descriptive of the history of Frederick I.; see *Sitzungsberichte d. Bairisch. Akad. d. Wissenschaft, Phil.-Hist. Klasse*, 1879, ii. 285. Its authenticity is called in question by Denifle, but it would seem to be quite in harmony with the known facts.

² The arts course of study was that represented by the ancient *trivium* (*i.e.*, grammar, logic, and rhetoric) and the *quadrivium* (*i.e.*, arithmetic, geometry, music, and astronomy), as handed down from the schools of the Roman empire. See J. B. Mullinger, *History of the University of Cambridge*, i. 24–27.

somewhat the earlier. It was developed, as that of the civil law had been developed, by a succession of able teachers, among whom Thaddeus Alderottus was especially eminent. The faculty of arts, down to the 14th century, scarcely attained to equal eminence. The teaching of theology remained for a long time exclusively in the hands of the Dominicans; and it was not until the year 1360 that Innocent VI. recognized the university as a "studium generale" in this branch,—in other words, as a place of theological education for all students, with the power of conferring degrees of universal validity.

Account
of the
univer-
sity by
Anglicus.

In the year 1371 the cardinal legate, Anglicus, compiled, as chief director of ecclesiastical affairs in the city, an account of the university, which he presented to Urban V. The information it supplies is, however, defective, owing to the fact that only the professors who were in receipt of salaries from the municipality are mentioned. Of these there were twelve of civil law and six of canon law; three of medicine, three of practical medicine, and one of surgery; two of logic, and one each of astrology, rhetoric, and notarial practice. The professors of theology, who, as members of the religious orders, received no state remuneration, are unmentioned.

The
earliest
colleges.

Colleges existed at Bologna at a very early date, but it is not until the 14th century that we find them possessing any organization. They were designed solely for necessitous students, not being natives of Bologna. A separate house, with a certain fund for the maintenance of a specified number of scholars, was all that was originally contemplated. Such was the character of that founded by Zoen, bishop of Avignon, in February 1256 (O.S.), the same month and year, it is to be noted, in which the Sorbonne was founded in Paris. It was designed for the maintenance of eight scholars from the province of Avignon, under the supervision of three canons of the church, maintaining themselves in the university. Each scholar was to receive 24 Bolognese lire annually for five years. The college of Brescia was founded in 1326 by William of Brescia, archdeacon of Bologna, for poor foreign students without distinction as to nationality. The Spanish college, founded in 1364, for twenty-four Spanish scholars and two chaplains, is noted by Denifle as the one college founded in mediæval times which still exists on the Continent.

Origin of
response to
university of
Paris.

Of the general fact that the early universities rose in response to new wants the commencement of the university of Paris supplies us with a further illustration. The study of logic, which, prior to the 12th century, was founded exclusively on one or two meagre compends, received about the year 1100, on two occasions, a powerful stimulus,—in the first instance, from the memorable controversy between Lanfranc and Berengar; in the second, from the no less famous controversy between Anselm and Roscellinus. A belief sprang up that an intelligent apprehension of spiritual truth depended on a correct use of prescribed methods of argumentation. Dialectic was looked upon as "the science of sciences"; and, when, somewhere in the first decade of the 12th century, William of Champeaux opened in Paris a school for the more advanced study of dialectic as an art, his teaching was attended with marked success. Among his pupils was Abelard, in whose hands the study made a yet more notable advance; so that, by the middle of the century, we find John of Salisbury, on returning from the French capital to England, relating with astonishment, not unmingled with contempt, how all learned Paris had gone well nigh mad in its pursuit and practice of the new dialectic.

Study of
logic.

Teaching
of
Abelard.

Abelard taught in the first instance at the cathedral school at Notre Dame, and subsequently at the schools on the Montagne Sainte-Geneviève, of which he was the

founder, and where he imparted to logic its new development. But in 1147 the secular canons of Ste Geneviève gave place to canons regular from St Victor; and henceforth the school on the former foundation was merely a school for the teaching of theology, and was attended only by the members of the house.¹ The schools out of which the university arose were those attached to the cathedral on the Île de la Cité, and presided over by the chancellor,—a dignitary who must be carefully distinguished from the later chancellor of the university. For a long time the teachers lived in separate houses on the island, and it was only by degrees that they combined themselves into a society, and that special buildings were constructed for their class-work. But the flame which Abelard's teaching had kindled was not destined to expire. Among his pupils was Peter Lombard, who was bishop of Paris in 1159, and widely known to posterity as the compiler of the famous volume of the *Sentences*. The design of this work was to place before the student, in as strictly logical a form as practicable, the views (*sententiæ*) of the fathers and all the great doctors of the church upon the chief and most difficult points in the Christian belief. Conceived with the purpose of allaying and preventing, it really stimulated, controversy. The logicians seized upon it as a great storehouse of indisputable major premises, on which they argued with renewed energy and with endless ingenuity of dialectical refinement; and upon this new compendium of theological doctrine, which became the text-book of the Middle Ages, the schoolmen, in their successive treatises *super Sententiis*, expended a considerable share of that subtlety and labour which still excite the astonishment of the student of metaphysical literature.

Lombard's
Sentences.

It is in these prominent features in the history of these early universities—the development of new methods of instruction concurrently with the appearance of new material for their application—that we find the most probable solution of the question as to how the university, as distinguished from the older cathedral or monastic schools, was first formed. In a similar manner, it seems probable, the majority of the earlier universities of Italy—Reggio, Modena, Vicenza, Padua, and Vercelli—arose, for they had their origin independently alike of the civil and the papal authority. Instances, it is true, occur, which cannot be referred to this spontaneous mode of growth. The university of Naples, for example, was founded solely by the fiat of the emperor Frederick II. in the year 1224; and, if we may rely upon the documents cited by Denifle, Innocent IV. about the year 1245 founded in connexion with the curia a "studium generale,"² which was attached to the papal court, and followed it when removed from Rome, very much as the Palace School of Charles the Great accompanied that monarch on his progresses.

Rise of
early universities—
the development of
new methods of
instruction concurrently
with the appearance
of new material for
their application.

As the university of Paris became the model, not only for the universities of France north of the Loire, but also for the great majority of those of central Europe as well as for Oxford and Cambridge, some account of its early organization will here be indispensable. Such an account is rendered still further necessary by the fact that the recent and almost exhaustive researches of Denifle, the Dominican father, have led him to conclusions which on some important points run altogether counter to those sanctioned by the high authority of Savigny.

Early
organization of
universities of
France.

The original university, as already stated, took its rise entirely out of the movement carried on by teachers on the

¹ The view of Thurot (*De l'Organisation de l'Enseignement dans l'Université de Paris*, pp. 4-7) that the university arose out of a combination of these several schools is rejected by Denifle (see *Die Universitäten*, &c., i. 653-694).

² Where the words *studium generale* are placed within marks of quotation they occur in the original charter of foundation of the university referred to.

The teaching that formed its nucleus.

island, who taught by virtue of the licence conferred by the chancellor of the cathedral. In the second decade of the 13th century, it is true, we find masters withdrawing themselves from his authority by repairing to the left bank of the Seine and placing themselves under the jurisdiction of the abbot of the monastery of Ste Geneviève; and in 1255 this dignitary is to be found appointing a chancellor whose duty it should be to confer "*licentia docendi*" on those candidates who were desirous of opening schools in that district. But it was around the bestowal of this licence by the chancellor of Notre Dame, on the Île de la Cité, that the university of Paris grew up. It is in this licence that the whole significance of the master of arts degree is contained; for what is technically known as admission to that degree was really nothing more nor less than receiving the chancellor's permission to "*incept*," and by "*inception*" was implied the master's formal entrance upon, and commencement of, the functions of a duly licensed teacher, and his recognition as such by his brothers in the profession. The previous stage of his academic career, that of bachelordom, had been one of apprenticeship for the mastership; and his emancipation from this state was symbolized by placing the magisterial cap (*biretta*) upon his head, a ceremony which, in imitation of the old Roman ceremony of manumission, was performed by his former instructor, "under whom" he was said to incept. He then gave a formal inaugural lecture, and, after this proof of magisterial capacity, was welcomed into the society of his professional brethren with set speeches, and took his seat in his master's chair.

Inception.

Bachelor of arts.

The university formed.

This community of teachers of recognized fitness did not in itself suffice to constitute a university, but some time between the years 1150 and 1170, the period when the *Sentences* of Peter Lombard were given to the world, the university of Paris came formally into being. Its first written statutes were not, however, compiled until about the year 1208, and it was not until long after that date that it possessed a "*rector*." Its earliest recognition as a legal corporation belongs to about the year 1211, when a brief of Innocent III. empowered it to elect a proctor to be its representative at the papal court. By this permission it obtained the right to sue or to be sued in a court of justice as a corporate body.

Difficulties attending its first development.

This papal recognition was, however, very far from implying the episcopal recognition, and the earlier history of the new community exhibits it as in continual conflict alike with the chancellor, the bishop, and the cathedral chapter of Paris, by all of whom it was regarded as a centre of insubordination and doctrinal licence. Had it not been, indeed, for the papal aid, the university would probably not have survived the contest; but with that powerful assistance it came to be regarded as the great Transalpine centre of orthodox theological teaching. Successive pontiffs, down to the great schism of 1378, made it one of the foremost points of their policy to cultivate friendly and confidential relations with the authorities of the university of Paris, and systematically to discourage the formation of theological faculties at other centres. In 1231 Gregory IX., in the bull *Parens Scientiarum*, gave full recognition to the right of the several faculties to regulate and modify the constitution of the entire university,—a formal sanction which, in Denifle's opinion, rendered the bull in question the Magna Charta of the university.

In comparing the relative antiquity of the universities of Paris and Bologna, it is difficult to give an unqualified decision. The university of masters at the former was probably slightly anterior to the university of students at the latter; but there is good reason for believing that Paris, in reducing its traditional customs to statutory form,

largely availed itself of the precedents afforded by the already existing code of the Transalpine centre, while its rectorship, proctorships, and four "*nations*" are all clearly distinct adaptations of the corresponding divisions at Bologna. These nations, which included both professors and scholars, were—(1) the French nation, composed, in addition to the native element, of Spaniards, Italians, and Greeks; (2) the Picard nation, representing the students from the north-east and from the Netherlands; (3) the Norman nation; (4) the English nation, comprising, besides students from the provinces under English rule, those from England, Ireland, Scotland, and Germany. These several nations first came into existence some time before the year 1219, and all belonged to the faculty of arts; but the fully developed university was divided into four faculties,—three "*superior*," viz., those of theology, canon law, and medicine, and one "*inferior*," that of arts. The head of each faculty was the dean; the head of each nation was the proctor. The rector, who in the first instance was head of the faculty of arts, by whom he was elected, was eventually head of the whole university. Each of the nations and each of the superior faculties, while subject to the general authority which he represented, was, like a royal colony, in a great measure self-governed, and made statutes which were binding simply on its own members. Congregations of the faculty of arts were presided over by the rector, who discharged the same function when general congregations of the whole academic community were convened. In the former the votes on any question were taken by nations, in the latter by faculties and nations. Only "*regents*," that is, masters actually engaged in teaching, had any right to be present or to vote in congregations. Neither the entire university nor the separate faculties had thus, it will be seen, originally a common head, and it was not until the middle of the 14th century that the rector became the head of the collective university, by the incorporation under him, first, of the students of the canon law and of medicine (which took place about the end of the 13th century), and, secondly, of the theologians, which took place about half a century later.

Apart from the broad differences in their organization, Paris and the very conception of learning, it will be observed, was different at Bologna from what it was at Paris. In the former it was entirely professional,—designed, that is to say, to prepare the student for a definite and practical career in after life; in the latter it was sought to provide a general mental training, and to attract the learner to studies which were speculative rather than practical.

In the sequel, the less mercenary spirit in which Paris cultivated knowledge added immensely to her influence and reputation. The university became known as the great school where theology was studied in its most scientific spirit; and the decisions of its great doctors upon those abstruse questions which absorbed so much of the highest intellectual activity of the Middle Ages were regarded as almost final. The popes themselves, although averse from theological controversies, deemed it expedient to cultivate friendly relations with a centre of such importance for the purpose of securing their influence in a yet wider field. Down therefore to the time of the great schism (1378), they at once conciliated the university of Paris and consulted what they deemed to be the interests of the Roman see, by discouraging the creation of faculties of theology elsewhere. The apparent exceptions to this policy are easily explained: the four faculties of theology which they sanctioned in Italy—Pisa (1343), Florence (1349), Bologna (1362), and Padua (1363)—were designed to benefit the Italian monasteries, by saving the monks the expense and dangers of a long journey beyond the Alps; while that at

The "nations."

Paris and Bologna contrasted.

Papal policy in relation to the universities.

Toulouse (1229) took its rise under circumstances entirely exceptional, being designed as a bulwark against the heresy of the Albigenses. The popes, on the other hand, favoured the creation of new faculties of law, and especially of the canon law, as the latter represented the source from which Rome derived her most warmly contested powers and prerogatives. The effects of this twofold policy were sufficiently intelligible: the withholding of each charter which it was sought to obtain for a new school of theology only served to augment the numbers that flocked to Paris; the bestowal of each new charter for a faculty of law served in like manner to divert a certain proportionate number from Bologna. These facts enable us to understand how it is that, in the 13th and 14th centuries, we find, even in France, a larger number of universities created after the model of Bologna than after that of Paris.

In their earliest stage, however, the importance of these new institutions was but imperfectly discerned alike by the civil and the ecclesiastical power, and the first four universities of Italy, after Bologna, rose into existence, like Bologna itself, without a charter from either pope or emperor. Of these the first were those of Reggio and Modena, both of which are to be found mentioned as schools of civil law before the close of the 12th century. The latter, throughout the 13th century, appears to have been resorted to by teachers of sufficient eminence to form a flourishing school, composed of students not only from the city itself, but also from a considerable distance. Both of them would seem to have been formed independently of Bologna, but the university of Vicenza was probably the outcome of a migration of the students from the former city, which took place in the year 1204. In the course of the century Vicenza attained to considerable prosperity; its students were divided into four nations, each with its own rector; and in 1264 it included in its professoriate teachers, not only of the civil law, but also of medicine, grammar, and dialectic. The university of Padua was founded in 1222 as the direct result of the migration of a considerable number of students from Bologna. Some writers, indeed, have inferred that the "studium" in the latter city was transferred in its entirety, but the continued residence of a certain proportion in Bologna is proved by the fact that two years later we find them appealing to Honorius III. in a dispute with the civic authorities. In the year 1228 the students of Padua were compelled by circumstances to transfer their residence to Vercelli, and the latter city guaranteed them, besides other privileges, the right to rent no less than five hundred lodging-houses at a fixed rental for a period of eight years. At first Padua was a school only of the civil and canon law; and during the oppressive tyranny of Ezzelin (1237-1260) the university maintained its existence with some difficulty. But in the latter part of the century it incorporated the faculties of grammar, rhetoric, and medicine, and became known as one of the most flourishing schools of Italy, and a great centre of the Dominicans, at that time among the most active promoters of learning.

The university of Naples was founded by the emperor Frederick II. in the year 1225, as a school of theology, jurisprudence, the arts, and medicine,—his design being that his subjects in the kingdom of Naples should find in the capital adequate instruction in every branch of learning, and "not be compelled in the pursuit of knowledge to have recourse to foreign nations or to beg in other lands." In the year 1231, however, he decreed that the faculty of medicine should cease to exist, and that the study should be pursued nowhere in the kingdom but at Salerno. The university never attained to much eminence, and after the death of Frederick came for a time altogether to an end, but was restored in 1258 by King Manfred. In 1266 its

faculty of medicine was reconstituted, and from 1272-74 Thomas Aquinas was one of its teachers of theology. The commencement of the university of Vercelli belongs to Vercelli, about the year 1228; it probably included, like Naples, all the faculties, but would seem to have been regarded with little favour by the Roman see, and by the year 1372 had ceased to exist, although mention of colleges of law and medicine is to be found after that date. The two universities of Piacenza and Pavia stand in close con-Piacenza, nexion with each other. The former is noted by Denifle as the earliest in Italy which was founded by virtue of a papal charter (6th February 1248), although the scheme remained for a long time inoperative. At length, in the year 1398, the university was reconstituted by Giovanni Galeazzo Visconti, duke of Milan, who in the same year caused the university of Pavia to be transferred thither. Piacenza now became the scene of a sudden but short-lived academic prosperity. We are told of no less than twenty-seven professors of the civil law,—among them the celebrated Baldus; of twenty-two professors of medicine; of professors of philosophy, astrology, grammar, and rhetoric; and of lecturers on Seneca and Dante. The faculty of theology would appear, however, never to have been duly constituted, and but one lecturer in this faculty is mentioned. With the death of Galeazzo in 1402, this precarious activity came suddenly to an end; and in 1404 the university had ceased to exist. Its history is, indeed, unintelligible, unless taken in conjunction with that of Pavia. Even before Pavia, Irnerius taught at Bologna, Pavia had been widely known as a seat of legal studies, and more especially of the Lombard law, although the evidence is wanting which would serve to establish a direct connexion between this early school and the university which was founded there in 1361, by virtue of the charter granted by the emperor Charles IV. The new "studium" included faculties of jurisprudence, philosophy, medicine, and the arts, and its students were formally taken under the imperial protection, and endowed with privileges identical with those which had been granted to Paris, Bologna, Oxford, Orleans, and Montpellier; but its existence in Pavia was suddenly suspended by the removal, above noted, of its students to Piacenza. It shared again in the decline which overtook the university of Piacenza after the death of Giovanni Galeazzo, and during the period from 1404 to 1412 it altogether ceased to exist. But in October 1412 the lectures were recommenced, and the university entered upon the most brilliant period of its existence. Its professors throughout the 15th century were men of distinguished ability, attracted by munificent salaries such as but few other universities could offer, while in the number of students who resorted thither from other countries, and more especially for the study of the civil law, Pavia had no rival in Italy but Padua. Arezzo appears to have been Arezzo, known as a centre of the same study so early as 1215, and its earliest statutes are assigned to the year 1255. By that time it had become a school of arts and medicine also; but for a considerable period after it was almost entirely deserted, and is almost unmentioned until the year 1338, when it acquired new importance by the accession of several eminent jurists from Bologna. In May 1355 it received its charter as a studium generale from Charles IV. After the year 1373 the school gradually dwindled, although it did not become altogether extinct until about the year 1470. The university of Rome (which is to be Rome, carefully distinguished from the school attached to the curia) owed its foundation (1303) to Boniface VIII., and was especially designed by that pontiff for the benefit of the poor foreign students sojourning in the capital. It originally included all the faculties; but in 1318 John XXII. decreed that it should possess the power of confer-

Founda-
tion of

Naples,

ring degrees only in the canon and civil law. The university maintained its existence throughout the period of the residence of the popes at Avignon (see POPedom), and under the patronage of Leo X. could boast in 1514 of no less than eighty professors. This imposing array would seem, however, to be but a fallacious test of the prosperity of the academic community, for it is stated that many of the professors, owing to the imperfect manner in which they were protected in their privileges, were in the receipt of such insufficient fees that they were compelled to combine other employments with that of lecturing in order to support themselves. An appeal addressed to Leo X. in the year 1513 represents the number of students as so small as to be sometimes exceeded by that of the lecturers ("ut quandoque plures sint qui legant quam qui audiant"). Scarcely any of the universities in Italy in the 14th century attracted a larger concourse than that of Perugia, where the study chiefly cultivated was that of the civil law. The university received its charter as a studium generale from Clement V. in the year 1308, but had already in 1306 been formally recognized by the civic authorities, by whom it was commended to the special care and protection of the "podestà." In common with the rest of the Italian universities, it suffered severely from the great plague of 1348-49; but in 1355 it received new privileges from the emperor, and in 1362 its first college, dedicated to Gregory the Great, was founded by the bishop of Perugia. The university of Treviso, which received its charter from Frederick the Fair in 1318, was of little celebrity and but short duration. It is doubtful, indeed, whether it continued to exist after the city became subject to the republic of Venice in the year 1339; but in 1409 the Venetian senate issued a decree that no subjects of the republic should resort for study to any city in its dominions save that of Padua, and from this date the studium at Treviso must be held to have been no longer in existence. The circumstances of the rise of the university of Florence are unknown, but the earliest evidence of academic instruction belongs to the year 1320. The dispersion of the university of Bologna, in the March and April of the following year, afforded a favourable opportunity for the creation of a studium generale, but the necessary measures were taken somewhat tardily, and in the meantime the greater number of the Bolognese students had betaken themselves to Siena. The charter of foundation for Florence was accordingly not granted until 31st May 1349, when Clement VI. decreed that there should be instituted a studium generale in theology, jurisprudence, medicine, and every other recognized faculty of learning, the teachers to be professors who had obtained the degree of doctor or master either at Bologna or Paris, or "some other studium generale of celebrity." On 2d January 1364 the university also obtained the grant of imperial privileges from Charles IV. On 14th February 1388 it adopted a body of statutes which are still extant, and afford an interesting study in connexion with the university history of the period. The university now entered upon that brilliant period in its history which was destined to so summary an extinction. "It is almost touching," says Denifle, "to note how untiringly Florence exerted herself at this period to attract as teachers to her schools the great masters of the sciences and learning." In the year 1472, however, under the influence of Lorenzo de' Medici, it was decided that Florence was not a convenient seat for a university, and its students were removed to Pisa. The commencement of the university of Siena belongs to about the year 1241, but its charter was first granted by the emperor Charles IV., at the petition of the citizens, in the year 1357. It was founded as a studium generale in jurisprudence, the arts, and medicine. The

imperial charter was confirmed by Gregory XII. in 1408, and the various bulls relating to the university which he subsequently issued afford a good illustration of the conditions of academic life in these times. Residence on the part of the students appears to have been sometimes dispensed with. The bishop of Siena was nominated chancellor of the university, just as, says the bull, he had been appointed to that office by the imperial authority. The graduates were to be admitted to the same privileges as those of Bologna or Paris; and a faculty of theology was added to the curriculum of studies. The university of Ferrara owes its foundation to the house of Este,—Alberto, marquis of Este, having obtained from Boniface IX. in 1391 a charter couched in terms precisely similar to those of the charter for Pisa. In the first half of the 15th century the university was adorned by the presence of several distinguished humanists, but its fortunes were singularly chequered, and it would appear for a certain period to have been altogether extinct. It was, however, restored, and became in the latter part of the century one of the most celebrated of the universities of Italy. In the year 1474 its circle of studies comprised all the existing faculties, and it numbered no less than fifty-one professors or lecturers. In later times Ferrara has been noted chiefly as a school of medicine.

Of the universities modelled on that of Paris, Oxford Oxford, would appear to have been the earliest, and the manner of its development was probably similar. Certain schools, opened within the precincts of the dissolved nunnery of St Frideswyde and of Oseney abbey, are supposed to have been the nucleus round which the university grew up. In the year 1133 one Robert Pullen, a theologian of considerable eminence (but whether an Englishman or a Breton is uncertain), arrived from Paris, and delivered lectures on the Bible. He was followed a few years later by Vacarius, a native of Lombardy, who as a student at Bologna had inherited the tradition of the teaching of Irnerius. Although both the pope and King Stephen regarded the civil law at this time with considerable distrust, Vacarius maintained his ground, and the study became one of the recognized faculties at Oxford. Towards the close of the 12th century Giraldus Cambrensis describes the town as a place "where the clergy in England chiefly flourished and excelled in clerical lore." In one respect, indeed, Oxford was more favoured than even Paris, for the town authorities could not pretend to assert any right of interference with the university such as that to which the French monarch and the court frequently laid claim. In the 13th century mention first occurs of university "chests," especially the Frideswyde chest, which were benefactions designed as funds for the assistance of poor students. Halls, or places of licensed residence for students, also began to be established. In the year 1257, when the bishop of Lincoln, as diocesan, had trenched too closely on the liberties of the community, the deputies from Oxford, when preferring their appeal to the king at St Albans, could venture to speak of the university as "schola secunda ecclesiarum," or second only to Paris. Its numbers about this time were probably some three thousand; but it was essentially a fluctuating body, and whenever plague or tumult led to a temporary dispersion a serious diminution in its numerical strength generally ensued for some time after. Against such vicissitudes the foundation of colleges proved the most effectual remedy. Of these the three earliest were University College, founded in 1249 by William of Durham; Balliol College, founded about 1263 by John Balliol, the father of the king of Scotland of the same name; and Merton College, founded in 1264. The last-named is especially notable as associated with a new conception of university education, namely, that of collegiate

discipline for the secular clergy, instead of for any one of the religious orders, for whose sole benefit all similar foundations had hitherto been designed. The statutes given to the society by Walter de Merton are not less noteworthy, as characterized not only by breadth of conception, but also by a careful and discriminating attention to detail, which led to their adoption as the model for later colleges, not only at Oxford but at Cambridge. Of the service rendered by these foundations to the university at large we have significant proof in the fact that, although representing only a small numerical minority in the academic community at large, their members soon obtained a considerable preponderance in the administration of affairs.

Cam-
bridge,

The university of Cambridge, although it rose into existence somewhat later than Oxford, may reasonably be held to have had its origin in the same century. There was probably a certain amount of educational work carried on by the canons of the church of St Giles, which gradually developed into the instruction belonging to a regular studium. In the year 1112 the canons crossed the river and took up their residence in the new priory in Barnwell, and their work of instruction acquired additional importance. Then, as early as the year 1224, the Franciscans established themselves in the town, and, somewhat less than half a century later, were followed by the Dominicans. At both the English universities, as at Paris, the Mendicants and other religious orders were admitted to degrees, a privilege which, until the year 1337, was extended to them at no other university. Their interest in and influence at these three centres was consequently proportionably great. In the years 1231 and 1233 certain royal and papal letters afford satisfactory proof that by that time the university of Cambridge was already an organized body with a chancellor at its head; and in 1229 and 1231 its numbers were largely augmented by migrations from Paris and from Oxford. Cambridge, however, in its turn suffered from emigration; while in the year 1261, and again in 1322, the records of the university were wantonly burnt by the townsmen. Throughout the 13th century, indeed, the university was still only a very slightly and imperfectly organized community. Its endowments were of the most slender kind; it had no systematic code for the government of its members; the supervision of the students was very imperfectly provided for. An important step in the direction of reform in this last respect was, however, made in the year 1276, when an ordinance was passed requiring that every one who claimed to be recognized as a scholar should have a fixed master within fifteen days after his entry into the university. But the feature which most served to give permanence and cohesion to the entire community was, as at Oxford, the institution of colleges. The earliest of these was Peterhouse, first founded as a separate institution by Hugh Balsham, bishop of Ely, in the year 1286, with a code which was little more than a transcript of that given by Walter de Merton to his scholars at Oxford. About forty years later was founded Michaelhouse, and at nearly the same time (1326) Edward II. instituted his foundation of "king's scholars," afterwards forming the community of King's Hall. Both these societies in the 16th century were merged in Trinity College. To those succeeded Pembroke Hall (1347) and Gonville Hall (1348). All these colleges, although by no means conceived in a spirit of hostility to either the monastic or the Mendicant orders, were expressly designed for the benefit of the secular clergy. The foundation of Trinity Hall (1350) by Bishop Bateman, on the other hand, as a school of civil and canon law was probably designed to further ultramontane interests. That of Corpus Christi (1352), the outcome of

the liberality of a guild of Cambridge townsmen, was conceived with the combined object of providing a house of education for the clergy, and at the same time securing the regular performance of masses for the benefit of the souls of departed members of the guild. But both Trinity Hall and Corpus Christi College, as well as Clare Hall, founded in 1359, were to a great extent indebted for their origin to the ravages caused among the clergy by the great plague of 1349.

Turning to France, or rather to the territory included Mont- within the boundaries of modern France, we find Mont- pellier, a recognized school of medical science as early as the 12th century. William VIII., lord of Montpellier, in the year 1181 proclaimed it a school of free resort, where any teacher of medical science, from whatever country, might give instruction. Before the end of the century it possessed also a faculty of jurisprudence, a branch of learning for which it afterwards became famed. The university of medicine and that of law continued, however, to be totally distinct bodies with different constitutions. Petrarch was sent by his father to Montpellier to study the civil law. On 26th October 1289 Montpellier was raised by Nicholas IV. to the rank of a "studium generale," a mark of favour which, in a region where papal influence was so potent, resulted in a considerable accession of prosperity. The university also now included a faculty of arts; and there is satisfactory evidence of the existence of a faculty of theology before the close of the 14th century, although not formally recognized by the pope before the year 1421. In the course of the same century several colleges for poor students were also founded. The university of Toulouse is to be noted as the first founded in any country by virtue of a papal charter. It took its rise in the efforts of Rome for the suppression of the Albigensian heresy, and its foundation formed one of the articles of the conditions of peace imposed by Louis IX. on Count Raymond of Toulouse. In the year 1233 it first acquired its full privileges as a "studium generale" by virtue of a charter given by Gregory IX. This pontiff watched over the university with especial solicitude, and through his exertions it soon became a noted centre of theological and especially of Dominican teaching. As a school of arts, jurisprudence, and medicine, although faculties of each existed, it never attained to any reputation. The university of Orleans had a virtual existence as a studium generale as early as the first half of the 13th century, but in the year 1305 Clement V. endowed it with new privileges, and gave its teachers permission to form themselves into a corporation. The schools of Orleans had an existence, it is said, as early as the 6th century, and subsequently supplied the nucleus for the foundation of a university at Blois; but of this university no records now exist.¹ Orleans, in its organization, was modelled mainly on Paris, but its studies were complementary rather than in rivalry to the older university. The absorbing character of the study of the civil law, and the mercenary spirit in which it was pursued, had led the authorities at Paris to refuse to recognize it as a faculty. The study found a home at Orleans, where it was cultivated with an energy which attracted numerous students. In January 1235 we find the bishop of Orleans soliciting the advice of Gregory IX. as to the expediency of countenancing a study which was prohibited in Paris. Gregory decided that the lectures might be continued; but he ordered that no beneficed ecclesiastic should be allowed to devote himself to so eminently secular a branch of learning. Orleans subsequently incorporated a faculty of arts, but its reputation from this period was always that of a school of legal studies, and in the 14th century its reputation in this respect was surpassed by no other uni-

¹ See Ch. Desmazes, *L'Université de Paris* (1200-1875).

- Angers, versity in Europe. Prior to the 13th century it had been famed for its classical learning; and Angers, which received its charter at the same time, also once enjoyed a like reputation, which, in a similar manner, it exchanged for that of a school for civilians and canonists. The roll of the university forwarded in 1378 to Clement VII. contains the names of 8 professors *utriusque juris*, 2 of civil and 2 of canon law, 72 licentiates, 284 bachelors of both the legal faculties, and 190 scholars. The university of Avignon, Avignon was first recognized as a "studium generale" by Boniface VIII. in the year 1303, with power to grant degrees in jurisprudence, arts, and medicine. Its numbers declined somewhat during the residence of the popes, owing to the counter attractions of the "studium" attached to the curia; but after the return of the papal court to Rome it became one of the most frequented universities in France, and possessed at one time no less than seven colleges. The university of Cahors, Cahors, the advantage of being regarded with especial favour by John XXII. In June 1332 he conferred upon it privileges identical with those already granted to the university of Toulouse. In the following October, again following the precedent established at Toulouse, he appointed the *scholasticus* of the cathedral chancellor of the university. In November of the same year a bull, couched in terms almost identical with those of the Magna Charta of Paris, assimilated the constitution of Cahors to that of the oldest university. The two schools in France which, down to the close of the 14th century, most closely resembled Paris were Orleans and Cahors. The civil immunities and privileges of the latter university were not, however, acquired until the year 1367, when Edward III. of England, in his capacity as duke of Aquitaine, not only exempted the scholars from the payment of all taxes and imposts, but bestowed upon them the peculiar privilege known as *privilegium fori*. Cahors also received a licence for faculties of theology and medicine, but, like Orleans, it was chiefly known as a school of jurisprudence. It was as a "studium generale" in the same three faculties that Grenoble, Grenoble, in the year 1339, received its charter from Benedict XII. The university never attained to much importance, and its annals are for the most part involved in obscurity. At the commencement of the 16th century it had ceased altogether to exist, was reorganized by Francis of Bourbon in 1542, and in 1565 was united to the university of Valence. Perpignan, The university of Perpignan, founded, according to Denifle, in 1379 by Clement VII. (although tradition had previously ascribed its origin to Pedro IV. of Aragon), and Orange, that of Orange, founded in 1365 by Charles IV., were universities only by name and constitution, their names rarely appearing in contemporary chronicles, while their very existence becomes at times a matter for reasonable doubt. Palencia, Huesca, Lerida, To some of the earlier Spanish universities—such as Palencia, founded about the year 1214 by Alfonso VIII.; Huesca, founded in 1354 by Pedro IV.; and Lerida, founded in 1300 by James II.—the same description is applicable; and their insignificance is probably indicated by the fact that they entirely failed to attract foreign students. Valladolid, Valladolid, founded in 1346 by Pope Clement VI., attained, however, to some celebrity; and the foreign teachers and students frequenting the university became so numerous that in 1373 King Henry II. caused an enactment to be passed for securing to them the same privileges as those already accorded to the native element. But the total number of the students in 1403 was only 116, and grammar and logic, along with jurisprudence (which was the principal study), constituted the sole curriculum. Whatever reputation, indeed, was enjoyed by Spain for nearly five centuries after the commencement of the university era, centred mainly in Salamanca, to which Seville,
- in the south, stood in the relation of a kind of subsidiary school, having been founded in 1254 by Alfonso the Wise, simply for the study of Latin and of the Semitic languages, especially Arabic. Salamanca was founded in 1243 by Ferdinand III. of Castile as a "studium generale" in the three faculties of jurisprudence, the arts, and medicine. Ferdinand extended his special protection to the students, granting them numerous privileges and immunities. Under his son Alfonso (above named) the university acquired a further development, and eventually included all the faculties save that of theology. But the main stress of its activity, as was the case with all the earlier Spanish universities, excepting only Palencia and Seville, until the commencement of the 15th century, was laid on the civil and the canon law. But, notwithstanding the favour with which Salamanca was regarded alike by the kings of Castile and by the Roman see, the provision for the payment of its professors was at first so inadequate and precarious that in 1298 they by common consent suspended their lectures, in consequence of their scanty remuneration. A permanent remedy for this difficulty was thereupon provided, by the appropriation of a certain portion of the ecclesiastical revenues of the diocese for the purpose of augmenting the professors' salaries. The earliest of the numerous colleges founded at Salamanca was that of St Bartholomew, long noted for its ancient library and valuable collection of manuscripts, which now form part of the royal library in Madrid. The one university possessed by Portugal had its seat Coimbra, in mediæval times alternately in Lisbon and in Coimbra, until, in the year 1537, it was permanently attached to the latter city. Its formal foundation took place in 1309, when it received from King Diniz a charter, the provisions of which were mainly taken from those of the charter given to Salamanca. In 1772 the university was entirely reconstituted. Of the German universities, Prague, which existed as a Prague, "studium" in the 13th century, was the earliest, and was at first frequented mainly by students from Styria and Austria, countries at that time ruled by the king of Bohemia. On 26th January 1347, at the request of Charles IV., Pope Clement VI. promulgated a bull authorizing the foundation of a "studium generale" in all the faculties. In the following year Charles himself issued a charter for the foundation. This document, which, if original in character, would have been of much interest, has but few distinctive features of its own, its provisions being throughout adapted from those contained in the charters given by Frederick II. for the university of Naples and by Conrad for Salerno,—almost the only important feature of difference being that Charles bestows on the students of Prague all the civil privileges and immunities which were enjoyed by the teachers of Paris and Bologna. Charles had himself been a student in Paris, and the organization of his new foundation was modelled on that university, a like division into four "nations" (although with different names) constituting one of the most marked features of imitation. The numerous students—and none of the mediæval universities attracted in their earlier history a larger concourse—were drawn from a gradually widening area, which at length included, not only all parts of Germany, but also England, France, Lombardy, Hungary, and Poland. Contemporary writers, with the exaggeration characteristic of mediæval credulity, even speak of thirty thousand students as present in the university at one time,—a statement for which Denifle proposes to substitute two thousand as a more probable estimate. It is certain, however, that Prague, prior to the foundation of Leipsic, was one of the most frequented centres of learning in Europe, and Paris suffered a considerable diminution in

her numbers owing to the counter attractions of the great studium of Slavonia.

Cracow, The university of Cracow in Poland was founded in May 1364, by virtue of a charter given by King Casimir the Great, who bestowed on it the same privileges as those possessed by the universities of Bologna and Padua. In the following September Urban V., in consideration of the remoteness of the city from other centres of education, constituted it a "studium generale" in all the faculties save that of theology. It is, however, doubtful whether these designs were carried into actual realization, for it is certain that, for a long time after the death of Casimir, there was no university whatever. Its real commencement must accordingly be considered to belong to the year 1400, when it was reconstituted, and the papal sanction was given for the incorporation of a faculty of theology. From this time its growth and prosperity were continuous; and with the year 1416 it had so far acquired a European reputation as to venture upon forwarding an expression of its views in connexion with the deliberations of the council of Constance. Towards the close of the 15th century the university is said to have been in high repute as a school of both astronomical and humanistic studies.

Vienna, The Avignonese popes appear to have regarded the establishment of new faculties of theology with especial jealousy; and when, in 1364, Duke Rudolph IV. founded the university of Vienna, with the design of constituting it a "studium generale" in all the faculties, Urban V. refused his assent to the foundation of a theological school. Owing to the sudden death of Duke Rudolph, the university languished for the next twenty years, but after the accession of Duke Albert III., who may be regarded as its real founder, it acquired additional privileges, and its prosperity became marked and continuous. Like Prague, Vienna was for a long time distinguished by the comparatively little attention bestowed by its teachers on the study of the civil law.

No country in the 14th century was looked upon with greater disfavour at Rome than Hungary. It was stigmatized as the land of heresy and schism. When, accordingly, in 1367 King Louis applied to Urban V. for his sanction of the scheme of founding a university at Fünfkirchen, although theological learning was in special need of encouragement in those regions, Urban would not consent to the foundation of a faculty of theology; he even made it a condition of his sanction for a "studium generale" that King Louis should first undertake to provide for the payment of the professors. We hear but little concerning the university after its foundation, and it is doubtful whether it survived for any length of time the close of the century, having been about that period absorbed in all probability in the university of Ofen. The foundation of this university is also involved in considerable obscurity, and its original charter is lost. We only know that it was granted by Boniface IX., at the request of King Sigismund, in the year 1389. In the first half of the 15th century it ceased for a long period to exist, but was revived, or rather founded afresh, by King Mathias Corvinus, an eminent patron of learning, in the last quarter of the century. "The extreme east of civilized continental Europe in mediæval times," observes Denifle, "can be compared, so far as university education is concerned, only with the extreme west and the extreme south. In Hungary, as in Portugal and in Naples, there was constant fluctuation, but the west and the south, although troubled by yet greater commotions than Hungary, bore better fruit. Among all the countries possessed of universities in mediæval times, Hungary occupies the lowest place—a state of affairs of which, however, the proximity of the Turk must be looked upon as a main cause."

The university of Heidelberg received its charter (23d October 1385) from Urban VI. as a "studium generale" in all the recognized faculties save that of the civil law,—the form and substance of the document being almost identical with those of the charter granted to Vienna. It was granted at the request of the elector palatine, Rupert I., who conferred on the teachers and students, at the same time, the same civil privileges as those which belonged to the university of Paris. In this case the functionary invested with the power of bestowing degrees was non-resident, the licences being conferred by the provost of the cathedral at Worms. But the real founder, as he was also the organizer and teacher, of the university was Marsilius of Inghen, to whose ability and energy Heidelberg was indebted for no little of its early reputation and success. The omission of the civil law from the studies licensed in the original charter would seem to show that the pontiff's compliance with the elector's request was merely formal, and Heidelberg, like Cologne, included the civil law among its faculties almost from its first creation. No mediæval university achieved a more rapid and permanent success. Regarded with favour alike by the civil and ecclesiastical potentates, its early annals were singularly free from crises like those which characterize the history of many of the mediæval universities. The number of those admitted to degrees from the commencement of the first session (19th October 1386 to 16th December 1387) amounted to 579.¹

Owing to the labours of the Dominicans, Cologne had gained a reputation as a seat of learning long before the founding of its university; and it was through the advocacy of some leading members of the Mendicant orders that, at the desire of the city council, its charter as a "studium generale" (21st May 1388) was obtained from Urban VI. It was organized on the model of the university of Paris, as a school of theology and canon law, and "any other recognized faculty,"—the civil law being incorporated as a faculty soon after the promulgation of the charter. In common with the other early universities of Germany—Prague, Vienna, and Heidelberg—Cologne owed nothing to imperial patronage, while it would appear to have been, from the first, the object of special favour with Rome. This circumstance serves to account for its distinctly ultramontane sympathies in mediæval times and even far into the 16th century. In a report transmitted to Gregory XIII. in 1577, the university expressly derives both its first origin and its privileges from the Holy See, and professes to owe no allegiance save to the Roman pontiff. Erfurt, no less noted as a centre of Franciscan than was Cologne of Dominican influence, received its charter (16th September 1379) from the anti-pope Clement VII. as a "studium generale" in all the faculties. Ten years later (4th May 1389) it was founded afresh by Urban VI., without any recognition of the act of his pretended predecessor. In the 15th century the number of its students was larger than that at any other German university—a fact attributable partly to the reputation it had acquired as a school of jurisprudence, and partly to the ardour with which the philosophic controversies of the time were debated in its midst.

The collegiate system is to be noted as a feature common to all these early German universities; and, in nearly all, the professors were partly remunerated by the appropriation of certain prebends, appertaining to some neighbouring church, to their maintenance.

Throughout the 15th century the relations of the Roman pontiffs to the universities continued much the same, although the independent attitude assumed at the great councils of Constance and Basel by the deputies from the

Relations of the popes to the universities.

¹ The statistics of Hautz (*Gesch. d. Univ. Heidelberg*, i. 177-8) are corrected by Denifle (*Die Entstehung der Universitäten*, v. 386).

universities, and especially by those from Paris, could not fail to excite their apprehensions. Their bulls for each new foundation begin again to indicate a certain jealousy with respect to the appropriation of prebends by the founders. Where such appropriations are made, and more particularly in France, a formal sanction of the transfer generally finds a place in the bull authorizing the foundation; while sometimes the founder or founders are themselves enjoined to provide the endowments requisite for the establishment and support of the university. In this manner the control of the pontiff over each newly-created seat of learning assumed a more real character, from the fact that his assent was accompanied by conditions which rendered it no longer a mere formality. The imperial intervention, on the other hand, was rarely invoked in Germany,—Greifswald, Freiburg, and Tübingen being the only instances in which the emperor's confirmation of the foundation was solicited.¹ But whatever influence the Roman see may have gained by increasing intervention was more than counteracted by those other tendencies which came into operation in the second half of the century. These were of a twofold character:—the first directly modifying the studies themselves, as the results of the discovery of printing and the new spirit awakened by the teaching of the humanists; the second affecting the external conditions, such as the multiplication of schools, and the growing demand for skilled physicians and learned civilians,—circumstances which afforded increased employment for the services of men of academic training. In northern Germany and in the Netherlands, the growing wealth and prosperity of the different states especially favoured the formation of new centres of learning. In the flourishing duchy of Brabant the university of Louvain (1426) was to a great extent controlled by the municipality; and their patronage, although ultimately attended with detrimental results, long enabled Louvain to outbid all the other universities of Europe in the munificence with which she rewarded her professors. In the course of the next century the “Belgian Athens,” as she is styled by Lipsius, ranked second only to Paris in numbers and reputation. In its numerous separate foundations and general organization—it possessed no less than twenty-eight colleges—it closely resembled the English universities; while its active press afforded facilities to the author and the controversialist of which both Cambridge and Oxford were at that time almost destitute. It embraced all the faculties, and no degrees in Europe stood so high as guarantees of general acquirements. Erasmus records it as a common saying, that “no one could graduate at Louvain without knowledge, manners, and age.” Sir William Hamilton speaks of the examination at Louvain for a degree in arts as “the best example upon record of the true mode of such examination, and, until recent times, in fact, the only example in the history of universities worthy of consideration at all.” He has translated from Vernulæus the order and method of this examination.² In 1788 the faculties of jurisprudence, medicine, and philosophy were removed to Brussels, and in 1797 the French suspended the university altogether. When Belgium was formed into an independent state in 1831, the university was refounded as a Roman Catholic foundation.

Founda-
tion of
Louvain,

Leipsic,

The circumstances of the foundation of the university of Leipsic are especially noteworthy, it having been the result of the migration of almost the entire German element from the university of Prague. This element comprised (1) Bavarians, (2) Saxons, (3) Poles (this last-named division being drawn from a wide area, which included Meissen, Lusatia, Silesia, and Prussia), and, being

represented by three votes in the assemblies of the university, while the Bohemians possessed but one, had acquired a preponderance in the direction of affairs which the latter could no longer submit to. Religious differences, again, evoked mainly by the preaching of John Huss, further intensified the existing disagreements; and eventually, in the year 1409, King Wenceslaus, at the prayer of his Bohemian subjects, issued a decree which exactly reversed the previous distribution of votes,—three votes being assigned to the Bohemian nation and only one to all the rest. The Germans took deep umbrage, and seceded to Leipsic, where, a bull having been obtained from Alexander V. (9th September 1409), a new “studium generale” was founded by the landgrave of Thuringia and the margraves of Meissen. The members were divided into four nations—composed of natives of Meissen, Saxony, Bavaria, and Poland. Two colleges were founded, a greater and a smaller, but designed, not for poor students, but for masters of arts,—twelve being admitted on the former and eight on the latter foundation. The first university of northern Germany was that of Rostock, founded by the dukes John and Albert of Mecklenburg, the scheme receiving the sanction of Martin V. in a bull dated 13th February 1419 as that of a “studium generale” in all the faculties excepting theology. The faculty of theology was added in the year 1432. Two colleges were also founded, with the same design and on the same scale as at Leipsic.

No little illustration is afforded by the circumstances attending the foundation of the French universities of the struggle that was going on between the crown and the Roman see. The earliest foundation in the 15th century was that of Poitiers. It was instituted by Charles VII. in 1431, almost immediately after his accession, with the special design of creating a centre of learning less favourable to English interests than Paris had at that time shown herself to be. Eugenius IV. could not refuse his sanction to the scheme, but he endeavoured partially to defeat Charles's design by conferring on the new “studium generale” only the same privileges as those possessed by Toulouse, and thus placing it at a disadvantage in comparison with Paris. Charles rejoined by an extraordinary exercise of his own prerogative, conferring on Poitiers all the privileges collectively possessed by Paris, Toulouse, Montpellier, Angers, and Orleans, and at the same time placing the university under special royal protection. The foundation of the university of Caen, in the diocese of Bayeux, was attended by conditions almost exactly the reverse of those which belonged to the foundation of that at Poitiers. It was founded under English auspices during the short period of the supremacy of the English arms in Normandy in the 15th century. Its charter (May 1437) was given by Eugenius IV., and the bishop of Bayeux was appointed its chancellor. The university of Paris had by this time completely forfeited the favour of Eugenius by its attitude at the council of Basel, and Eugenius inserted in the charter for Caen a clause of an entirely novel character, requiring all those admitted to degrees to take an oath of fidelity to the see of Rome, and to bind themselves to attempt nothing prejudicial to her interests. To this proviso the pragmatic sanction of Bourges was the reply given by Charles in the following year. On 18th May 1442 we find King Henry VI. writing to Eugenius, and dwelling with satisfaction on the rapid progress of the new university, to which, he says, students had flocked from all quarters, and were still daily arriving.³ On 30th October 1452 its charter was given afresh by Charles in terms which left the original charter unrecognized; both teachers and learners were made subject to the civil authorities of the city, while all privileges conferred in the former charter

¹ Meiners, *Gesch. d. hohen Schulen*, i. 370.

³ Bekynnton's *Correspondence*, i. 123.

in cases of legal disputes were abolished. From this time the university of Caen was distinguished by its loyal spirit and firm resistance to ultramontane pretensions; and, although swept away at the French Revolution, it was afterwards restored, owing to the sense of the services it had thus once rendered to the national cause.¹ No especially notable circumstances characterize the foundation of the university of Bordeaux (1441) or that of Valence (1452), but that of Nantes, which received its charter from Pius II. in 1463, is distinguished by the fact that it did not receive the ratification of the king of France, and the conditions under which its earlier traditions were formed thus closely resemble those of Poitiers. It seems also to have been regarded with particular favour by Pius II., a pontiff who was at once a ripe scholar and a writer upon education. He gave to Nantes a notable body of privileges, which not only represent an embodiment of all the various privileges granted to universities prior to that date, but afterwards became, with their copious and somewhat tautological phraseology, the accepted model for the great majority of university charters, whether issued by the pope or by the emperor, or by the civil authority. The bishop of Nantes was appointed head of the university, and was charged with the special protection of its privileges against all interference from whatever quarter.² The bull for the foundation of the university of Bourges was given in 1465 by Paul II. at the request of Louis XI. and his brother. It confers on the community the same privileges as those enjoyed by the other universities of France. The royal sanction was given at the petition of the citizens; but, from reasons which do not appear, they deemed it necessary further to petition that their charter might also be registered and enrolled by the parlement of Paris.

In Germany, the first of the universities representing the new influences above referred to is that of Greifswald. A wealthy burgomaster, who had graduated as a master of arts at Rostock, was the chief mover; and, his proposal being cordially seconded by the city council, the duke of the province, and certain abbots of neighbouring monasteries, the necessary bull was obtained from Calixtus III. (29th May 1456). The first session was commenced in October of the same year. Three colleges were at the same time founded,—two for masters of arts, as at Leipsic and Rostock, and a third for jurists. The chairs in the different faculties were distributed as follows: theology 3, jurisprudence 5, medicine 1, arts 4,—the number of jurists showing that the study of the civil law still obtained a certain preponderance. The university of Freiburg was founded by the archduke Albert, brother of the emperor Frederick III.,—the papal bull being given 20th April 1455, and the imperial ratification in the following year. The first session was opened in 1460, under the presidency of Matthew Hummel, a privy councillor, and the original numbers soon received considerable additions by secessions from Vienna and from Heidelberg. The endowment was further augmented by an annual allowance from the city council, and by certain canonries and livings attached to neighbouring parishes. In the same year, and probably in a spirit of direct rivalry, was opened the university of Basel. The cathedral school in that ancient city, together with others attached to the monasteries, afforded a sufficient nucleus for a "studium," and Pius II., who, as Æneas Sylvius, had been a resident in the city, was easily prevailed upon to grant the charter (12th November 1459). In the character of its endowments, and in the relative importance attached to the study of the civil law, Basel much resembled Greifswald, but its success throughout the 15th century was marred by the languid character of the

support afforded it by the civic authorities. Before he had signed the bull for the foundation of the university of Basel, Pius II., at the request of duke William of Bavaria, had issued another bull for the foundation of a university at Ingolstadt (7th April 1459). But it was not until 1472 that the work of teaching was actually commenced there. Some long-existing prebends, founded by former dukes of Bavaria, were appropriated to the endowment, and the chairs in the different faculties were distributed as follows:—theology 2, jurisprudence 3, medicine 1, arts 6,—arts in conjunction with theology thus obtaining the preponderance. As at Caen, twenty-two years before, an oath of fidelity to the Roman pontiff was imposed on every student admitted to a degree.³ That this proviso was not subsequently abolished, as at Caen, is a feature in the history of the university of Ingolstadt which was attended by important results. Nowhere did the Reformation meet with more stubborn resistance, and it was at Ingolstadt that the Counter-Reformation was commenced. In 1556 the Jesuits made their first settlement in the university.

The next two universities took their rise in the archiepiscopal seats of Treves and Mainz. That at Treves received its charter as early as 1450; but the first academical session did not commence until 1473. Here the ecclesiastical influences appear to have been unfavourable to the project. The archbishop demanded 2000 florins as the price of his sanction. The cathedral chapter threw difficulties in the way of the appropriation of certain livings and canonries to the university endowment; and so obstinate was their resistance that in 1655 they succeeded in altogether rescinding the gift on payment of a very inadequate sum. It was not until 1722 that the assembly of deputies, by a formal grant, relieved the university from the difficulties in which it had become involved. The university of Mainz, on the other hand, was almost entirely indebted to the archbishop Diether for its foundation. It was at his petition that Sixtus IV. granted the charter, 23d November 1476; and Diether, being himself an enthusiastic humanist, thereupon circulated a letter, couched in elegant Latinity, addressed to students throughout his diocese, inviting them to repair to the new centre, and dilating on the advantages of academic studies and of learning. The rise of these two universities, however, neither of which attained to much distinction, represents little more than the incorporation of certain already existing institutions into a homogeneous whole, the power of conferring degrees being superadded. But the university of Tübingen, founded by charter of Sixtus IV. (9th November 1476), represents an entirely new creation. Its real founder was Mathilda, the mother of Count Eberhard of Würtemberg, who appropriated five livings and eight prebends to the endowment. Of the chairs, 3 were for theology, 3 for the canon and 2 for the civil law, 2 for medicine, and 4 for arts. The general financial condition of this university in the year 1541–42, and the sources from whence its revenues were derived, have been illustrated by Hoffmann in a short paper which shows the fluctuating character of the resources of a university in those days,—liable to be affected, as they were, both by the seasons and the markets.⁴

Nearly contemporaneous with these foundations were Upsala those of Upsala (1477) and Copenhagen (1479), which, although lying without the political boundaries of Germany, reflected her influence. The charter for Copenhagen was given by Sixtus IV. as early as 1475. The students

attracted to this new centre were mainly from within the radius of the university of Cologne, and its statutes were little more than a transcript of those of the latter foundation.

Witten-
berg,

The electorates of Wittenberg and Brandenburg were now the only two considerable German territories which did not possess a studium generale, and the university founded at Wittenberg by Maximilian I. (6th July 1502) is notable as the first established in Germany by virtue of an imperial as distinguished from a papal decree. Its charter is, however, drawn up with the traditional phraseology of the pontifical bulls, and is evidently not conceived in any spirit of antagonism to Rome. Wittenberg is constituted a "studium generale" in all the four faculties,—the right to confer degrees in theology and canon law having been sanctioned by the papal legate some months before, 2d February 1502. The endowment of the university with church revenues duly received the papal sanction,—a bull of Alexander VI. authorizing the appropriation of twelve canonries attached to the castle church, as well as of eleven prebends in outlying districts—*ut sic per omnem modum unum corpus ex studio et collegio prædictis fiat et constituatur*. No university in Germany attracted to itself a larger share of the attention of Europe at its commencement. And it was its distinguishing merit that it was the first academic centre north the Alps where the antiquated methods and barbarous Latinity of the scholastic era were overthrown. The last university founded in Germany prior to the Reformation was that of Frankfurt-on-the-Oder. The design, first conceived by the elector John of Brandenburg, was carried into execution by his son Joachim, at whose request Pope Julius II. issued a bull for the foundation, 15th March 1506. An imperial charter, identical in its contents with the papal bull, followed on 26th October. The university received an endowment of canonries and livings similar to that of Wittenberg, and some houses in the city were assigned for its use by the elector.

Frank-
fort-on-
the-Oder,

St An-
drews,

The first university in Scotland was that of St Andrews, founded in 1411 by Henry Wardlaw, bishop of that see, and modelled chiefly on the constitution of the university of Paris. It acquired all its three colleges—St Salvator's, St Leonard's, and St Mary's—before the Reformation,—the first having been founded in 1456 by Bishop James Kennedy; the second in 1512 by the youthful archbishop Alexander Stuart (natural son of James IV.) and John Hepburn, the prior of the monastery of St Andrews; and the third, also in 1512, by the Beaton, who in the year 1537 procured a bull from Pope Paul III. dedicating the college to the Blessed Virgin Mary of the Assumption, and adding further endowments. The most ancient of the universities of Scotland, with its three colleges, was thus reared in an atmosphere of mediæval theology, and undoubtedly designed as a bulwark against heresy and schism. But "by a strange irony of fate," it has been observed, "two of these colleges became, almost from the first, the foremost agents in working the overthrow of that church which they were founded to defend." St Leonard's more especially, like St John's or Queens' at Cambridge, became a noted centre of intellectual life and Reformation principles. That he "had drunk at St Leonard's well" became a current expression for implying that a theologian had imbibed the doctrines of Protestantism. The university of Glasgow was founded as a "studium generale" in 1453, and possessed two colleges. Prior to the Reformation it acquired but little celebrity; its discipline was lax, and the number of the students but small, while the instruction was not only inefficient but irregularly given; no funds were provided for the maintenance of regular lectures in the higher faculties; and there was no adequate executive power for the maintenance of discipline. The uni-

Glasgow,

versity of Aberdeen, which was founded in 1494, at first Aberdeen possessed only one college,—namely, King's. Marischal College, founded in 1593 by George Keith, fifth Earl Marischal, was constituted by its founder independent of the university in Old Aberdeen, being itself both a college and a university, with the power of conferring degrees. Bishop Elphinstone, the founder both of the university and of King's College (1505), had been educated at Glasgow, and had subsequently both studied and taught at Paris and at Orleans. To the wider experience which he had thus gained we may probably attribute the fact that the constitution of the university of Aberdeen was free from the glaring defects which then characterized that of the university of Glasgow.¹ But in all the mediæval universities of Germany, England, and Scotland, modelled as they were on a common type, the absence of adequate discipline was, in a greater or less degree, a common defect. In connexion with this feature we may note the comparatively small percentage of matriculated students proceeding to the degrees of B.A. and M.A. when compared with later times. Of this disparity the following table, exhibiting the relative numbers in the university of Leipsic for every ten years from the year 1427 to 1552, probably affords a fair average illustration,—the remarkable fluctuations probably depending quite as much upon the comparative healthiness of the period (in respect of freedom from epidemic) and the abundance of the harvests as upon any other cause:—

The German universities in these times seem to have admitted for the most part their inferiority in learning to older and more favoured centres; and their consciousness of the fact is shown by the efforts which they made to attract instructors from Italy, and by the frequent resort of the more ambitious students to schools like Paris, Bologna, Padua, and Pavia. That they took their rise in any spirit of systematic opposition to the Roman see (as Meiners and others have contended), or that their organization was something external to and independent of the church, is sufficiently disproved by the foregoing evidence. Generally speaking, they were eminently conservative bodies, and the new learning of the humanists and the new methods of instruction that now began to demand attention were alike for a long period unable to gain admission within academic circles. Reformers such as Hegius, John Wessel, and Rudolphus Agricola carried on their work at places like Deventer remote from university influences. That there was a considerable amount of mental activity going on in the universities themselves is not to be denied; but it was mostly of that unprofitable kind which, while giving rise to endless controversy, turned upon questions in connexion with which the implied postulates and the terminology employed rendered all scientific investi-

gation hopeless. At almost every university—Leipsic, Greifswald, and Prague (after 1409) being the principal exceptions—the so-called Realists and Nominalists represented two great parties occupied with an internecine struggle. At Paris, owing to the overwhelming strength of the theologians, the Nominalists were indeed under a kind of ban; but at Heidelberg they had altogether expelled their antagonists. It was much the same at Vienna and at Erfurt,—the latter, from the ready reception which it gave to new speculation, being styled by its enemies “*novorum omnium portus*.” At Basel, under the leadership of the eminent Johannes a Lapide, the Realists with difficulty maintained their ground. Freiburg, Tübingen, and Ingolstadt, in the hope of diminishing controversy, arrived at a kind of compromise, each party having its own professor, and representing a distinct “nation.” At Mainz the authorities adopted a manual of logic which was essentially an embodiment of Nominalistic principles.

Abandonment of logical studies in Italy.

In Italy, almost without exception, it was decided that these controversies were endless, and that their effects were pernicious. It was resolved, accordingly, to expel logic, and allow its place to be filled by rhetoric. It was by virtue of this decision, which was of a tacit rather than a formal character, that the expounders of the new learning in the 15th century, men like Emmanuel Chrysoloras, Guarino, Leonardo Bruni, Bessarion, Argyropoulos, and Valla, carried into effect that important revolution in academic studies which constitutes a new era in university learning, and largely helped to pave the way for the Reformation.¹ This discouragement of the controversial spirit, continued as it was in relation to theological questions after the Reformation, obtained for the Italian universities a fortunate immunity from dissensions like those which, as we shall shortly see, distracted the centres of learning in Germany. The professorial body also attained to an almost unrivalled reputation. It was exceptionally select, only those who were in receipt of salaries being permitted, as a rule, to lecture; it was also famed for its ability, the institution of concurrent chairs proving an excellent stimulus. These chairs were of two kinds—“ordinary” and “extraordinary,”—the former being the more liberally endowed and fewer in number. For each subject of importance there were thus always two and sometimes three rival chairs, and a powerful and continuous emulation was thus maintained among the teachers. “From the integrity of their patrons, and the lofty standard by which they were judged,” says Sir W. Hamilton, “the call to a Paduan or Pisan chair was deemed the highest of all literary honours. The status of professor was in Italy elevated to a dignity which in other countries it has never reached; and not a few of the most illustrious teachers in the Italian seminaries were of the proudest nobility of the land. While the universities of other countries had fallen from Christian and cosmopolite to sectarian and local schools, it is the peculiar glory of the Italian that, under the enlightened liberality of their patrons, they still continued to assert their European universality. Creed and country were in them no bar,—the latter not even a reason of preference. Foreigners of every nation are to be found among their professors; and the most learned man in Scotland (Dempster) sought in a Pisan chair that theatre for his abilities which he could not find at home.”²

Events producing divisions in university history.

The Reformation represents the great boundary line in the history of the mediæval universities, and also, for a long time after, the main influence in the history of those new foundations which subsequently arose in Protestant countries. Even in Catholic countries its secondary effects

were scarcely less perceptible, as they found expression in connexion with the Counter-Reformation. In Germany the Thirty Years' War was attended by consequences which were felt long after the 17th century. In France the Revolution of 1789 resulted in the actual uprooting of the university system.

The influences of the New Learning, and the special character which it assumed as it made its way in Germany in connexion with the labours of scholars like Erasmus, John Reuchlin, Ulrich von Hutten, and Melancthon, augured well for the future. It was free from the frivolities, the pedantry, the immoralities, and the scepticism which characterized so large a proportion of the corresponding culture in Italy. It gave promise of resulting at once in a critical and enlightened study of the masterpieces of classical antiquity, and in a reverent and yet rational interpretation of the Scriptures and the fathers. The fierce Per-nicious influences of bigotry and the ceaseless controversies evoked by the promulgation of Lutheran or Calvinistic doctrine dispelled, however, this hopeful prospect, and converted what might otherwise have become the tranquil abodes of the Muses into gloomy fortresses of sectarianism. Of the manner in which it affected the highest culture, the observation of Henke in his *Life of Calixtus* (i. 8), that for a century after the Reformation the history of Lutheran theology becomes almost identified with that of the German universities, may serve as an illustration.

The first Protestant university was that of Marburg, Marburg, founded by Philip the Magnanimous, landgrave of Hesse, 30th May 1527. Expressly designed as a bulwark of Lutheranism, it was mainly built up out of the confiscation of the property of the religious orders in the Hessian capital. The house of the Dominicans, who had fled on the first rumour of spoliation, was converted into lecture-rooms for the faculty of jurisprudence. The church and convent of the order known as the “Kugelherrn” was appropriated to the theological faculty. The friary of the Barefooted Friars was shared between the faculties of medicine and philosophy. The university, which was the object of the margrave's peculiar care, rapidly rose to celebrity; it was resorted to by students from remote countries, even from Greece, and its professors were of distinguished ability. How much, however, of this popularity depended on its theological associations is to be seen in the fact that after the year 1605, when, by the decree of Count Maurice, its formulary of faith was changed from Lutheran to Calvinistic, its numbers greatly declined. This dictation of the temporal power now becomes one of the most notable features in academic history in Protestant Germany. The universities, having repudiated the papal authority, while that of the episcopal order was at an end, now began to pay especial court to the temporal ruler, and sought in every way to conciliate his goodwill, representing with peculiar distinctness the theory,—*cujus regio, ejus religio*. This tendency was further strengthened by the fact that their colleges, bursaries, and other similar foundations were no longer derived from or supported by ecclesiastical institutions, but were mainly dependent on the civil power.

The Lutheran university of Königsberg was founded 17th Königs-
August 1544 by Albert III., margrave of Brandenburg, berg.
and the first duke of Prussia, and his wife Dorothea, a Danish princess. In this instance, the religious character of the foundation not having been determined at the commencement, the papal and the imperial sanction were both applied for, although not accorded. King Sigismund of Poland, however, which kingdom exercised at that time a protectorate over the Prussian duchy, ultimately gave the necessary charter (29th September 1561), at the same time ordaining that all students who graduated as masters in the faculty of philosophy should rank as nobles of the

¹ For an excellent account of this movement, see Georg Voigt, *Die Wiederbelebung des classischen Alterthums*, 2d ed., 2 vols., 1880.

² Hamilton, *Discussions*, 2d ed., p. 373.

Polish kingdom. When Prussia was raised to the rank of a kingdom (1701) the university was made a royal foundation, and the "collegium Fridericianum," which was then erected, received corresponding privileges. In 1862 the university buildings were rebuilt, and the number of the students is now nearly one thousand.

Jena. The Lutheran university of Jena had its origin in a gymnasium founded by John Frederick the Magnanimous, elector of Saxony, during his imprisonment, for the express purpose of promoting Evangelical doctrines and repairing the loss of Wittenberg, where the Philippists had gained the ascendancy. Its charter, which the emperor Charles V. refused to grant, and which was obtained with some difficulty from his brother, Ferdinand I., eventually enabled the authorities to open the university, 2d February 1558. Distinguished for its vehement assertion of Lutheran doctrine, its hostility to the teaching of Wittenberg was hardly less pronounced than that with which both centres regard Roman Catholicism. For a long time it was chiefly noted as a school of medicine, and in the 17th and 18th centuries it was in bad repute for the lawlessness of its students, among whom duelling prevailed to a scandalous extent. The beauty of its situation and the eminence of its professoriate have, however, generally attracted a considerable proportion of students from other countries. Its numbers in 1885 were 566.

Helmstädt. The Lutheran university of Helmstädt, founded by Duke Julius (of the house of Brunswick-Wolfenbüttel), and designated after him in its official records as "Academia Julia," received its charter, 8th May 1575, from the emperor Maximilian II. No university in the 16th century commenced under more favourable auspices. It was munificently endowed by the founder and by his son; and its "Convictorium," or college for poor students, expended in the course of thirty years no less than 100,000 thalers, an extraordinary expenditure for an institution of such a character in those days. Beautifully and conveniently situated in what had now become the well-peopled region between the Weser and the lower Elbe, and distinguished by its comparatively temperate maintenance of the Lutheran tenets, it attracted a considerable concourse of students, especially from the upper classes, not a few being of princely rank. Throughout its history, until suppressed in 1809, Helmstädt enjoyed the special and powerful patronage of the dukes of Saxony.

Altdorf. The "Gymnasium Ægidianum" of Nuremberg, founded in 1526, and removed in 1575 to Altdorf, represents the origin of the university of Altdorf. A charter was granted in 1578 by the emperor Rudolph II., and the university was formally opened in 1580. It was at first, however, empowered only to grant degrees in arts; but in 1623 the emperor Ferdinand II. added the permission to create doctors of law and medicine, and also to confer crowns on poets; and in 1697 its faculties were completed by the permission given by the emperor Leopold I. to create doctors of theology. Like Louvain, Altdorf was nominally ruled by the municipality, but in the latter university this power of control remained practically inoperative, and the consequent freedom enjoyed by the community from evils like those which brought about the decline of Louvain is thus described by Hamilton:—"The decline of that great and wealthy seminary (Louvain) was mainly determined by its vicious patronage, both as vested in the university and in the town. Altdorf, on the other hand, was about the poorest university in Germany, and long one of the most eminent. Its whole endowment never rose above £800 a year; and, till the period of its declension, the professors of Altdorf make at least as distinguished a figure in the history of philosophy as those of all the eight universities of the British empire together. On looking

closely into its constitution the anomaly is at once solved. The patrician senate of Nuremberg were too intelligent and patriotic to attempt the exercise of such a function. The nomination of professors, though formally ratified by the senate, was virtually made by a board of four curators; and what is worthy of remark, as long as curatorial patronage was a singularity in Germany, Altdorf maintained its relative pre-eminence, losing it only when a similar mean was adopted in the more favoured universities of the empire."¹

The conversion of Marburg into a school of Calvinistic doctrine gave occasion to the foundation of the universities of Giessen and of Rinteln. Of these the former, founded by the margrave of Darmstadt, Louis V., as a kind of refuge for the Lutheran professors from Marburg, received its charter from the emperor Rudolph II., 19th May 1607. When, however, the margraves of Darmstadt acquired possession of Marburg in 1625, the university was transferred thither; in 1650 it was moved back again to Giessen. The number of matriculated students at the commencement of the century was about 250; in 1887 it was 484. In common with the other universities of Germany, but with a facility which obtained for it a specially unenviable reputation, Giessen was for a long time wont to confer the degree of doctor *in absentia* in the different faculties without requiring adequate credentials. This practice, however, which drew forth an emphatic protest from the eminent historian Mommsen, has within the last few years been entirely abandoned. The university of Rinteln was founded 17th July 1621 by the emperor Ferdinand II. Almost immediately after its foundation it became the prey of contending parties in the Thirty Years' War, and its early development was thus materially hindered. It never, however, attained to much distinction, and in 1819 it was suppressed. The university of Strasburg was founded in 1621 on the basis of an already existing academy, to which the celebrated John Sturm stood, during the latter part of his life, in the relation of "rector perpetuus," and of which we are told that in 1578 it included more than a thousand scholars, among whom were 200 of the nobility, 24 counts and barons, and three princes. It also attracted students from all parts of Europe, and especially from Portugal, Poland, Denmark, France, and England. The method of Sturm's teaching became the basis of that of the Jesuits, and through them of the public school instruction in England. In 1621 Ferdinand II. conferred on this academy full privileges as a university; in the language of the charter, "in omnibus facultatibus, doctores, licentiatos, magistros, et baccalaureos, atque insuper *poetas laureatos* creandi et promovendi."² In 1681 Strasburg became French, and remained so until 1870.

The university of Dorpat (now Russian) was founded by Gustavus Adolphus in 1632, and reconstituted by the emperor Alexander I. in 1802. A special interest attaches to this university from the fact that it has for a long time been the scene of the contending influences of Teutonism and Slavonianism. Situated in Livonia, which at the time of its foundation represented a kind of debateable land between Russia and Poland, its gradual monopoly by the former country has not been without resistance and protests on the part of that Teutonic element which was at one time the more potent in its midst. The study of the Slavonic languages has here received considerable stimulus, and by a decree in May 1887 the use of the Russian language having been made obligatory in all places of instruction through the Baltic provinces, Russian has now taken the place of German as the language of the lecture-room. Dorpat possesses a fine library of over 80,000 volumes, and is also noted for its admirable botanical collection. The

Prague.

Russian minister has also recently instituted a professorship of the comparative grammar of the Slavonic dialects (now filled by J. Baudouin de Courtenay). The general influence of the university has been rapidly extending during the last few years far beyond the Baltic provinces. The number of students, which in 1879 was 1106, in 1886 was 1751.¹ A like contest between contending nationalities has recently met with a final solution at Prague, where a Czech university has been established on an independent basis, the German university having commenced its separate career in the winter session of 1882-83. The German foundation retains its endowments, but the state subvention is divided between the two.

Bam-
berg.

The repudiation on the part of the Protestant universities of both papal and episcopal authority evoked a counter-demonstration among those centres which still adhered to Catholicism, while their theological intolerance gave rise to a great reaction, under the influence of which the mediæval Catholic universities were reinvigorated and reorganized (although strictly on the traditional lines), while new and important centres were created. It was on the tide of this reaction, aided by their own skill and sagacity, that the Jesuits were borne to that commanding position which made them for a time the arbiters of education in Europe. The earliest university whose charter represented this reaction was that of Bamberg, founded by the prince-bishop Melchior Otto, after whom it was named "Academia Ottoniana." It was opened 1st September 1648, and received both from the emperor Frederick III. and Pope Innocent X. all the civil and ecclesiastical privileges of a mediæval foundation. At first, however, it comprised only the faculties of arts and of theology; to these was added in 1729 that of jurisprudence, and in 1764 that of medicine. In this latter faculty Dr Ignatius Döllinger (the father of the historian) was for a long time a distinguished professor. The university of Innsbruck was founded in 1672 by the emperor Leopold I., from whom it received its name of "Academia Leopoldina." In the following century, under the patronage of the empress Maria Theresa, it made considerable progress, and received from her its ancient library and bookshelves in 1745. In 1782 the university underwent a somewhat singular change, being reduced by the emperor Joseph II. from the status of a university to that of a lyceum, although retaining in the theological faculty the right of conferring degrees. In 1791 it was restored to its privileges by the emperor Leopold II., and since that time the faculties of philosophy, law, and medicine have been represented in nearly equal proportions. In 1886 the number of professors was 74, and of students 869. The foundation of the university of Breslau was contemplated as early as the year 1505, when Ladislaus, king of Hungary, gave his sanction to the project, but Pope Julius II., in the assumed interests of Cracow, withheld his assent. Nearly two centuries later, in 1702, under singularly altered conditions, the Jesuits prevailed upon the emperor Leopold I. to found a university without soliciting the papal sanction. When Frederick the Great conquered Silesia in 1741, he took both the university and the Jesuits in Breslau under his protection, and when in 1774 the order was suppressed by Clement XIV. he established them as priests in the Royal Scholastic Institute, at the same time giving new statutes to the university. In 1811 the university was considerably augmented by the incorporation of that at Frankfort-on-the-Oder. At the present time it possesses both a Catholic and a Lutheran faculty. Its medical faculty is in high repute. The total number of students in 1887 was 1347.

universities more marked than in France. The civil wars in that country during the thirty years which preceded the close of the 16th century told with disastrous effects upon the condition of the university of Paris, and with the commencement of the 17th century its collegiate life seemed at an end, and its forty colleges stood absolutely deserted. To this state of affairs the obstinate conservatism of the academic authorities not a little contributed. The statutes by which the university was still governed were those which had been given by the cardinal D'Estouteville, the papal legate, in 1452, and remained entirely unmodified by the influences of the Renaissance. In 1579 the edict of Blois promulgated a scheme of organization for all the universities of the realm (at that time twenty-one in number),—a measure which, though productive of unity of teaching, did nothing towards the advancement of the studies themselves. The eminent lawyers of France, unable to find chairs in Paris, distributed themselves among the chief towns of the provinces. The Jesuits did not fail to profit by this immobility and excessive conservatism on the part of the university, and during the second half of the 16th century and the whole of the 17th they had contrived to gain almost a complete monopoly of both the higher and the lower education of provincial France. Their schools arose at Toulouse and Bordeaux, at Auch, Agen, Rhodéz, Périgueux, Limoges, Le Puy, Aubenas, Béziers, Tournon, in the colleges of Flanders and Lorraine, Douai and Pont-à-Mousson,—places beyond the jurisdiction of the parlement of Paris or even of the crown of France. Their banishment from Paris itself had been by the decree of the parlement alone, and had never been confirmed by the crown. "Lyons," says Pattison, "loudly demanded a Jesuit college, and even the Huguenot Lesdiguières, almost king in Dauphiné, was preparing to erect one at Grenoble. Amiens, Rheims, Rouen, Dijon, and Bourges were only waiting a favourable opportunity to introduce the Jesuits within their walls."² The university was rescued from the fate which seemed to threaten it only by the excellent statutes given by Richer in 1598, and by the discerning protection extended to it by Henry IV.

The "college of Edinburgh" was founded by charter of James VI., dated 14th April 1582. This document contains no reference to a studium generale, nor is there ground for supposing that the foundation of a university was at that time contemplated. In marked contrast to the three older centres in Scotland, the college rose comparatively untrammelled by the traditions of mediævalism, and its creation was not effected without some jealousy and opposition on the part of its predecessors. Its first course of instruction was commenced in the Kirk of Field, under the direction of Robert Rollock, who had been educated at St Andrews under Andrew Melville, the eminent Covenanter. "He began to teach," says Craufurd, "in the lower hall of the great lodging, there being a great concourse of students allured with the great worth of the man; but diverse of them being not ripe enough in the Latin tongue, were in November next put under the charge of Mr Duncan Narne, . . . who, upon Mr Rollock's recommendation, was chosen second master of the college."³ In 1585 both Rollock and Narne subscribed the National Covenant, and a like subscription was from that time required from all who were admitted to degrees in the college.

Disastrous as were the effects of the Thirty Years' War upon the external condition of the German universities, resulting in not a few instances in the total dispersion of the students and the burning of the buildings and libraries, they were less detrimental and less permanent than those which were discernible in the tone and temper of these

communities. A formal pedantry and unintelligent method of study, combined with a passionate dogmatism in matters of religious belief, and a rude contempt for the amenities of social intercourse, became the leading characteristics, and lasted throughout the 17th century. But in the year 1693 the foundation of the university of Halle opened up a career to two very eminent men, whose influence, widely different as was its character, may be compared for its effects with that of Luther and Melancthon, and served to modify the whole current of German philosophy and German theology. Halle has indeed been described as "the first real modern university." It was really indebted for its origin to a spirit of rivalry between the conservatism of Saxony and the progressive tendencies of the house of Brandenburg, but the occasion of its rise was the removal of the ducal court from Halle to Magdeburg. The archbishopric of the latter city having passed into the possession of Brandenburg in 1680 was changed into a dukedom, and the city itself was selected as the ducal residence. This change left unoccupied some commodious buildings in Halle, which it was decided to utilize for purposes of education. A "Ritterschule" for the sons of the nobility was opened, and in the course of a few years it was decided to found a university. Saxony endeavoured to thwart the scheme, urging the proximity of Leipsic; but her opposition was overruled by the emperor Leopold I., who granted (19th October 1693) the requisite charter, and in the following year the work of the university commenced. Frankfurt-on-the-Oder had by this time become a centre of the Reformed party, and the primary object in founding a university in Halle was to create a centre for the Lutheran party, but its character, under the influence of its two most notable teachers, Christian Thomasius and A. H. Francke, soon expanded beyond the limits of this conception to assume a highly original form. Thomasius and Francke had both been driven from Leipsic owing to the disfavour with which their liberal and progressive tendencies were there regarded by the academic authorities, and on many points the two teachers were in agreement. They both regarded with contempt alike the scholastic philosophy and the scholastic theology; they both desired to see the rule of the civil power superseding that of the ecclesiastical power in the seats of learning; they were both opposed to the ascendancy of classical studies as expounded by the humanists—Francke regarding the Greek and Roman pagan writers with the old traditional dislike, as immoral, while Thomasius looked upon them with contempt, as antiquated and representing only a standpoint which had been long left behind; both again agreed as to the desirability of including the elements of modern culture in the education of the young. But here their agreement ceased. It was the aim of Thomasius, as far as possible, to secularize education, and to introduce among his countrymen French habits and French modes of thought; his own attire was gay and fashionable, and he was in the habit of taking his seat in the professorial chair adorned with gold chain and rings, and with his dagger by his side. Francke, who became the leader of the Pietists, regarded all this with even greater aversion than he did the lifeless orthodoxy traditional in the universities, and was shocked at the worldly tone and disregard for sacred things which characterized his brother professor. Both, however, commanded a considerable following among the students. Thomasius was professor in the faculty of jurisprudence, Francke in that of theology. And it was a common prediction in those days with respect to a student who proposed to pursue his academic career at Halle, that he would infallibly become either an atheist or a Pietist. But the services rendered by Thomasius to learning were genuine and lasting. He was the first to set the example, soon

after followed by all the universities of Germany, of lecturing in the vernacular instead of in the customary Latin; and the discourse in which he first departed from the traditional method was devoted to the consideration of how far the German nation might with advantage imitate the French in matters of social life and intercourse. His more general views, as a disciple of the Cartesian philosophy and founder of the modern Rationalismus, exposed him to incessant attacks; but by the establishment of a monthly journal (at that time an original idea) he obtained a channel for expounding his views and refuting his antagonists which gave him a great advantage. On the influence of Francke, as the founder of that Pietistic school with which the reputation of Halle afterwards became especially identified, it is unnecessary here to dilate.¹ J. C. Wolf, who followed Thomasius as an assertor of the new culture, was driven from Halle by the accusations of the Pietists, who declared that his teaching was fraught with atheistical principles. In 1740, however, he was recalled by Frederick II., and reinstated in high office with every mark of consideration and respect. Throughout the whole of the 18th century Halle was the leader of academic thought and culture in Protestant Germany, although sharing that leadership, after the middle of the century, with Göttingen. The university of Göttingen (named after its founder "Georgia gen. Augusta") was endowed with the amplest privileges as a university by George II. of England, elector of Hanover, 7th December 1736. The imperial sanction of the scheme had been given three years before (13th January 1733), and the university was formally opened 17th September 1737. The king himself assumed the office of "rector magnificentissimus," and the liberality of the royal endowments (doubling those of Halle), and the not less liberal character of the spirit that pervaded its organization, soon raised it to a foremost place among the schools of Germany. Halle had just expelled Wolf; and Göttingen, modelled on the same lines as Halle, but rejecting its Pietism and disclaiming its intolerance, appealed with remarkable success to the most enlightened feeling of the time. It included all the faculties, and two of its first professors—Mosheim, the eminent theologian, from Helmstädt, and Böhmer, the no less distinguished jurist, from Halle—together with Gesner, the man of letters, at once established its reputation. Much of its early success was also due to the supervision of its chief curator (there were two),—Baron Münchhausen, himself a man of considerable attainments, who by his sagacious superintendence did much to promote the general efficiency of the whole professoriate. Not least among its attractions was also its splendid library, located in an ancient monastery, and now containing over 200,000 volumes and 5000 MSS. In addition to its general influence as a distinguished seat of learning, Göttingen may claim to have been mainly instrumental in diffusing a more adequate conception of the importance of the study of history. Before the latter half of the 18th century the mode of treatment adopted by university lecturers was singularly wanting in breadth of view. Profane history was held of but little account, excepting so far as it served to illustrate ecclesiastical and sacred history, while this, again, was invariably treated in the narrow spirit of the polemic, intent mainly on the defence of his own confession, according as he represented the Lutheran or the Reformed Church. The labours of the professors at Göttingen, especially Putter, Gatterer, Schlözer, and Spittler, combined with those of Mascov at Leipsic, did much towards promoting both a more catholic treatment and a wider scope. Not less beneficial was the example set at Göttingen of securing the appointment of its professors by a less prejudiced and partial body than a university

¹ See Paulsen, *Gesch. des gelehrten Unterrichts*, &c., pp. 348–358.

board is only too likely to become. "The great München, says an illustrious professor of that seminary, 'allowed our university the right of presentation, of designation, or of recommendation, as little as the right of free election; for he was taught by experience that, although the faculties of universities may know the individuals best qualified to supply their vacant chairs, *they are seldom or never disposed to propose for appointment the worthiest within their knowledge.*'"¹ The system of patronage adopted at Göttingen was, in fact, identical with that which had already been instituted in the universities of the Netherlands by Douza (see *infra*, p. 850). The university of Erlangen, a Lutheran centre, was founded by Frederick, margrave of Baireuth. Its charter was granted by the emperor Charles VII., 21st February 1743, and the university was formally constituted, 4th November. From its special guardian, Alexander, the last margrave of Ansbach, it was styled "Academia Alexandrina." In 1791, Ansbach and Baireuth having passed into the possession of Prussia, Erlangen became subject to the Prussian Government. The number of the students, which at the commencement of the century was under 300, was 880 in 1887.

Erlangen.

The English and German universities compared.

On comparison with the great English universities, the universities of Germany must be pronounced inferior both in point of discipline and of moral control over the students. The superiority of the former in these respects is partly to be attributed to the more systematic care which they took, from a very early date, for the supervision of each student, by requiring that within a certain specified time after his entry into the university he should be registered as a pupil of some master of arts, who was responsible for his conduct, and represented him generally in his relations to the academic authorities. Marburg in its earliest statutes (those of 1529) endeavoured to establish a similar rule, but without success.² The development of the collegiate system at Oxford and Cambridge materially assisted the carrying out of this discipline. Although again, as in the German universities, feuds were not unfrequent, especially those between "north" and "south" (the natives of the northern and southern counties), the fact that in elections to fellowships and scholarships only a certain proportion were allowed to be taken from either of these divisions acted as a considerable check upon the possibility of any one college representing either element exclusively. In the German universities, on the other hand, the ancient division into nations, which died out with the 15th century, was revived under another form by the institution of national colleges, which largely served to foster the spirit of rivalry and contention. The demoralization induced by the Thirty Years' War and the increase of duelling intensified these tendencies, which, together with the tyranny of the older over the younger students, known as "Pennalismus," were evils against which the authorities contended, but ineffectually, by various ordinances. The institution of "Burschenthum," having for its design the encouragement of good fellowship and social feeling irrespective of nationality, served only as a partial check upon these excesses, which again received fresh stimulus by the rival institution of "Landmannschaften," or societies of the same nationality. The latter proved singularly provocative of duelling, while the arrogant and even tyranni-

cal demeanour of their members towards the unassociated students gave rise to a general combination of the latter for the purposes of self-defence and organized resistance. At all the great German universities both these forms of association are to be found existing at the present day.

The political storms which marked the close of the last Extinction and the commencement of the present century gave the death-blow to not a few of the ancient universities of Germany. Mainz and Cologne ceased to exist in 1798; Bamberg, Dillingen, and Duisberg in 1804; Rinteln and Helmstädt in 1809; Salzburg in 1810; Erfurt in 1816, 1798-1815. Altdorf was united to Erlangen in 1807, Frankfurt-on-the-Oder to Breslau in 1809, and Wittenberg to Halle in 1815. The university of Ingolstadt was first moved in 1802 to Landshut, and from thence in 1826 to Munich, Munich, where it was united to the academy of sciences which was founded in the Bavarian capital in 1759. Of those of the above centres which altogether ceased to exist but few, however, were much missed or regretted,—that at Mainz, which had numbered some six hundred students, being the one notable exception. The others had for the most part fallen into a perfunctory and lifeless mode of teaching, and, with wasted or diminished revenues and declining numbers, had long ceased worthily to represent the functions of a university. Whatever loss may have attended their suppression has been far more than compensated by the activity and influence of the three great German universities which have risen in the present century. Munich has become a distinguished centre of study in all the faculties; and its numbers, allowing for the two great wars, have been continuously on the increase. The number of its professors in 1887 was over ninety, and that of its students at the commencement of the session 1886-87 3209.

The university of Berlin, known as the Royal Friedrich Wilhelm university, was founded in 1809, immediately after the peace of Tilsit, when Prussia had been reduced to the level of a third-rate power. Under the guiding influence of Wilhelm von Humboldt, however, the principles which were adopted in connexion with the new seat of learning not only raised it to a foremost place among the universities of Europe, but also largely conduced to the regeneration of Germany. A notable characteristic in the university of Berlin at the time of its foundation was its entire repudiation of attachment to any particular creed or school of thought, and professed subservience only to the interests of science and learning. "Each of the eminent teachers with whom the university began its life—F. A. Wolf, Fichte, Savigny, Reil—represented only himself, the path of inquiry or the completed theory which he had himself propounded. Its subsequent growth was astonishing. In 1813 Berlin had only 36 teachers altogether; in 1860 there were 173 in all,—97 professors, 66 privatdozenten, and 7 lecturers." In 1886 there were 296 teachers and 5357 students; and among the former a large proportion of the names are already of world-wide reputation, while its classical school stands unrivalled in Europe.

The university of Bonn, founded in 1818, and known Bonn, as the Rhenish Friedrich Wilhelm university, has 88 professors and 1125 students. Equally distinguished as a school of philosophy and a school of theology, it is notable for the manner in which it combines the opposed schools of theological doctrine,—that of the Evangelical (or Lutheran) Church and that of the Roman Catholic Church here standing side by side, and both adorned by eminent names. This combination (which also exists at Tübingen and at Breslau) has been attended with complete success and (according to Dr Döllinger) with unmistakable advantages. When tried, however, a generation before, at Erfurt and at Heidelberg, its failure was not less conspicuous, and Erfurt was ruined by the experiment.

¹ Hamilton, *Discussions*, p. 381.

² "Volumus neminem in hanc nostram Academiam admitti, aut per rectorem in album recipi, qui non habeat privatum atque domesticum præceptorem, qui ejus discipulum agnoscat, ad cujus judicium quisque pro sua ingenii capacitate atque Marte lecturas et publicas et privatas audiat, a cujus latere aut raro aut nunquam discedat." Koch expressly compares this provision with the discipline of Oxford and Cambridge, which, down to the commencement of the present century, was very much of the same character (Koch, *Gesch. des akademischen Pädagogiums in Marburg*, p. 11).

Statistics
of Ger-
man and
British
univer-
sities
com-
pared.

Dr Conrad, professor of political science at Halle, has recently made the statistics relating to the German universities the subject of a careful investigation and analysis, which offer some interesting results. The total cost of the universities of the German empire is shown to be much smaller than the total revenues of the English universities and colleges, although the number both of professors and students is much larger, and although 42 per cent. of the total expenditure is upon establishments, such as hospitals, museums, and so forth. But in Germany 72 per cent. of the cost of the universities is defrayed by the state, the students paying, in the shape of fees, only 9.3 per cent. To a great extent, however, the German universities are to be looked upon as professional schools, giving an education which directly fits a man to earn his bread as a clergyman, a lawyer, a judge, a physician, a schoolmaster, a chemist, an engineer, or an agriculturist. Notwithstanding the rapid growth in the numbers of the students, the growth of the professoriate has fully kept pace with it. In 1880 there were 1809 teachers at work in the German universities, more than half of whom (967) were full professors ("ordinarii"),—the proportion of teachers to students being 1 to 11. This is a much higher proportion than that of Oxford and Cambridge, although in them there is a large staff of college lecturers, which is practically more important than the university staff. It is higher again than the proportion of the Scottish universities, where there are only some 105 professors to between 5000 and 6000 students, a proportion of 1 to between 50 and 60 students. The increase in Germany has taken place partly by adding on fresh teachers for the old subjects, such as Latin and Greek, but still more by founding new chairs for new subjects, such as Oriental and Romance languages, geography, and archaeology, and by subdividing departments which have been recently developed, such as those connected with political economy, political science, physiology, and biology. Owing to the great development of natural science, the faculty of philosophy has at some centres increased to such an extent as to equal in numbers all the other faculties put together. This inconvenience has been

differently met at different universities. In those of Switzerland, no further remedy has been devised than that of appointing separate syndicates or boards of management for the two main divisions,—the philosophico-historic and the mathematical and natural-scientific; at Dorpat, Tübingen, and Strasburg, on the other hand, these divisions have been represented by the formation of two distinct faculties; while Tübingen, Munich, and Würzburg have created, in addition, a third faculty under which are grouped the several subjects of political economy, statistics, and finance.

The following table (taken from Conrad) exhibits the average of the total number of matriculated students at the German universities for every five years from 1831 to 1884; it brings the tendency to form large centres very forcibly before the view. The three largest at Ger-centres—Berlin, Leipsic, Munich—even in the first quinquennium appear as absorbing no less than 35 per cent. of the students, and in the last as many as 42 per cent. At the same time, there has lately been a no less notable increase among the centres of second magnitude. A quarter of a century ago only two universities had more than a thousand students; at present there are nine.

Fluctuations of numbers.

Universities of United Provinces.

Leyden.

Franeker.

In 1878 a comparison of the numbers of the students in the different faculties in the Prussian universities with those for the year 1867 showed a remarkable diminution in the faculty of theology, amounting in Lutheran centres to more than one-half, and in Catholic centres to nearly three-fourths. In jurisprudence there was an increase of nearly two-fifths, in medicine a decline of a third, and in philosophy an increase of one-fourth. During the last few years, however, the faculties of theology have made some progress towards regaining their former numbers.

The universities of the United Provinces, like those of Protestant Germany, were founded by the state as schools for the maintenance of the principles of the Reformation and the education of the clergy, and afforded in the 16th and 17th centuries a grateful refuge to not a few of those Huguenot or Port-Royalist scholars whom persecution compelled to flee beyond the boundaries of France, as well as to the Puritan clergy who were driven from England. The earliest, that of Leyden, founded in 1575, commemorated the gallant and successful resistance of the citizens to the Spanish fleet under Requesens. Throughout the 17th century Leyden was distinguished by its learning, the ability of its professors, and the shelter it afforded to the more liberal thought associated at that period with Arminianism. Much of its early success was owing to the wise provisions and the influence of the celebrated Janus Douza:—"Douza's principles," says Hamilton, "were those which ought to regulate the practice of all academical patrons; and they were those of his successors. He knew that at the rate learning was seen prized by the state in the academy would it be valued by the nation at large. . . . He knew that professors wrought more even by example and influence than by teaching, that it was theirs to pitch high or low the standard of learning in a country, and that, as it proved easy or arduous to come up with them, they awoke either a restless endeavour after an even loftier attainment, or lulled into a self-satisfied conceit." Douza was, for Leyden and the Dutch, what Münchausen afterwards was for Göttingen and the German universities. "But with this difference: Leyden was the model on which the younger universities of the republic were constructed; Göttingen the model on which the older universities of the empire were reformed. Both Münchausen and Douza proposed a high ideal for the schools founded under their auspices; and both, as first curators, laboured with paramount influence in realizing this ideal for the same long period of thirty-two years. Under their patronage Leyden and Göttingen took the highest place among the universities of Europe; and both have only lost their relative supremacy by the application in other seminaries of the same measures which had at first determined their superiority." The appointment of the professors at Leyden was vested in three (afterwards five) curators, one of whom was selected from the body of the nobles, while the other two were appointed by the states of the province,—the office being held for nine years, and eventually for life. With these was associated the mayor of Leyden for the time being. The university of Franeker was founded in 1585 on a somewhat less liberal basis than Leyden, the professors being required to declare their assent to the rule of faith embodied in the Heidelberg Catechism and the confession of the "Belgian Church." Its four faculties were those of theology, jurisprudence, medicine, and "the three languages and the liberal arts."¹ For a period of twelve years (*circa* 1610–1622) the reputation of the university was enhanced by the able teaching of William Ames ("Amesius"), a Puritan divine and moralist who had been driven by Bancroft from Cambridge and from England. His fame and ability are said to have

attracted to Franeker students from Hungary, Poland, and Russia.

With like organization were founded—in 1600 the university of Harderwijk, in 1614 that of Groningen, and in 1634 that of Utrecht. The restoration of the House of Orange, and establishment of the kingdom of the Netherlands (23d March 1815), was followed by important changes in connexion with the whole kingdom. The universities of Franeker and Harderwijk were suppressed, while their place was taken by the newly-founded centres at Ghent (1816) and Liège (1816). A uniform constitution was given both to the Dutch and Belgian universities. It was also provided that there should be attached to each a board of curators, consisting of five persons, "distinguished by their love of literature and science and by their rank in society." These curators were to be nominated by the king, and at least three of them chosen from the province in which the university was situated, while the other two were to be chosen from adjacent provinces. After the redivision of the kingdom in 1831, Ghent and Liège were constituted state universities, and each received a subsidy from the Government (see BELGIUM). The university of Brussels, on the other hand, founded in 1834, is an independent institution, supported by the liberal party; while the reconstituted university at Louvain represents the party of Roman Catholicism, and is almost exclusively a theological school for the education of the Catholic clergy. The universities of Belgium are, however, somewhat heterogeneous bodies, and present in their organization a singular combination of French and German institutions. In Holland, the foundation of the university of Amsterdam (1877) has more than repaired the loss of Franeker and Harderwijk, and the progress of this new centre during the ten years of its existence has been remarkably rapid, so that it bids fair to rival, if not to outstrip, both Utrecht and Leyden. The higher education of women has made some progress in the Netherlands; and in 1882–83 there were eighteen women studying at Amsterdam, eleven at Groningen, four at Leyden, and seven at Utrecht.

In Sweden the university of Lund, founded in 1668 and modelled on the same plan as its predecessor at Upsala, has adhered to its antiquated constitution with remarkable tenacity. At both these universities the mediæval division into "nations" is still in force among the students, the number at Upsala being no less than thirteen. The professoriate at both centres is much below the modern requirements in point of numbers. The university of Christiania in Norway, founded in 1811, and the Swedish universities are strongly Lutheran in character; and all alike are closely associated with the ecclesiastical institutions of the Scandinavian kingdoms. The same observation applies to Copenhagen,—where, however, the labours of Rask and Madvig have done much to sustain the reputation of the university for learning. The university of Kiel (1665), on the other hand, has come much more under Teutonic influences, and is now a distinguished centre of scientific teaching.

In France the fortunes of academic learning were even less happy than in Germany. The university of Paris was distracted, throughout the 17th century, by theological dissensions,—in the first instance owing to the struggle that ensued after the Jesuits had effected a footing at the Collège de Clermont, and subsequently by the strife occasioned by the teaching of the Jansenists. Its studies, discipline, and numbers alike suffered. Towards the close of the century a certain revival took place, and a succession of illustrious names—Pourchot, Rollin, Grenan, Coffin, Demontempuys, Crevier, Lebeau—appear on the roll of its teachers. But this improvement was soon interrupted by the controversies excited by the promulgation

¹ *Statuta et Leges*, Franeker, 1647, p. 3.

of the bull *Unigenitus* in 1713, condemning the tenets of Quesnel, when Rollin himself, although a man of singularly pacific disposition, deemed it his duty to head the opposition to Clement XI. and the French episcopate. At last, in 1762, the parlement of Paris issued a decree (August 6) placing the colleges of the Jesuits at the disposal of the university, and this was immediately followed by another for the expulsion of the order from Paris. Concurrently with this measure the prospects of the university assumed a more favourable character, the curriculum of its studies was extended, and both history and natural science began to be cultivated with a certain success. These better prospects were, however, soon obscured by the outbreak of the Revolution; and on the 15th September 1793 the universities and colleges throughout France, together with the faculties of theology, medicine, jurisprudence, and arts, were abolished by a decree of the Convention. The Collège de France, when restored in 1831, was reconstituted mainly as a school of adult instruction, for the most part of a popular character, and entirely dissociated from the university. It now numbers thirty-nine chairs, among which is one of the Slavonic languages and literature. The university of France (which succeeded to that of Paris) is at present little more than an abstract term, signifying the whole of the professional body under state control, and comprising various faculties at different centres—Paris, Montpellier, Nancy, &c., together with twenty-seven academical rectorates. Each of these rectors presides over a local "conseil d'enseignement," in conjunction with which he elects the professors of lycées and the communal schoolmasters, whose formal appointment is then made by the minister of public instruction. There are ecclesiastics in some of the conseils d'enseignement, but the rectors are all laymen who have graduated in one of the faculties. The great schools have also in no small measure supplemented the work of the universities by their advance in the direction of scientific instruction. Among the number the "École Pratique des Hautes Études" in Paris (31st July 1868) and the "École Polytechnique," which traces its origin as far back as the year 1794, are especially distinguished. The course of instruction at the former is divided into five sections—(1) mathematics, (2) physics and chemistry, (3) natural history and physiology, (4) history and philology, (5) economic science. At the latter the instruction is conceived solely with regard to the application of scientific principles to all branches of the public service, but more especially the military and mercantile. In 1875 the National Assembly passed an Act which enabled the Roman Catholic body to establish free universities of their own, and to confer degrees which should be of the same validity as those of the state university. At Lille and Angers such centres have been already organized. The university of Strasbourg, which in the latter part of the last century had been distinguished by an intellectual activity which became associated with the names of Goethe, Herder, and others, was also swept away by the Revolution. It was, however, restored 1st May 1872, after the city had reverted to Germany, and was remodelled entirely on German principles. Since then its success has been marked and continuous.

In Switzerland all the higher education is supported mainly by the German and Protestant cantons. The four universities of Basel, Bern, Zurich, and Geneva have an aggregate of some 1400 or 1500 students, and all possess faculties of philosophy, jurisprudence, theology, and medicine. Basel is, however, the chief centre for theology, as is Bern for jurisprudence and Zurich for philosophy. At Geneva the famous academy of the 16th and 17th centuries, long distinguished as a centre of Calvinistic teaching, is now represented by a university (first formed in 1876),

where the instruction is given (mainly in the French language) by a staff of forty-one professors, and where there is a rising school of science. Switzerland almost takes the lead in connexion with female education on the Continent, and in 1882–83 there were 52 women at the university of Geneva, 36 at Bern, and 24 at Zurich.

In Spain the universities at present existing are those of Barcelona, Granada, Madrid (transferred in 1837 from Alcalá), Oviedo, Salamanca, Santiago, Seville, Valencia, Valladolid, and Zaragoza. They are all, with the exception perhaps of Madrid, in a lamentably depressed condition, and mainly under the influence of French ideas and modelled on French examples. But in Portugal, Coimbra, which narrowly escaped suppression in the 16th century as a suspected centre of political disaffection, is now a flourishing school. Its instruction is given gratis; but, as all members of the higher courts of judicature and administration in the realm are required to have graduated at the university, it is at the same time one of the most aristocratic schools in Europe. There are five faculties, viz., theology, jurisprudence, medicine, mathematics, and philosophy. Of these, that of law is by far the most flourishing, the number of students in this faculty nearly equalling the aggregate of all the rest. There is a valuable library, largely composed of collections formerly belonging to suppressed convents. As a school of theology Coimbra is distinctly anti-ultramontane, and the progressive spirit of the university is shown by the fact that the rector has been instructed by the government to devise a scheme for the admission of women.

In Italy the universities are numerically much in excess of the requirements of the population, there being no less than sixteen state universities and four free universities. Very few of these possess theological faculties, and in no country are theological studies less valued. Education for the church is almost entirely given at the numerous "seminaries," where it is of an almost entirely elementary character. In 1875 a laudable effort was made by Bonghi, the minister of education, to introduce reforms and to assimilate the universities in their organization and methods to the German type. His plans were, however, to a great extent reversed by his successor, Coppino.

In Austria the universities, being modelled on the same of system as that of Prussia, present no especially noteworthy features. Vienna is chiefly distinguished for its school of medicine, which enjoyed in the last century a reputation almost unrivalled in Europe. The other faculties were, however, suffered to languish, and throughout the first half of the present century the whole university was in an extremely depressed state. From this condition it was in a great measure restored by the exertions of Count Thun. The number of the matriculated students in 1887 was 4893, and that of the professors 138; among the latter the names of Zschokke, Maassen, Sickel, Jellinek, and Büdinger are some of the most widely known. The university of Olmütz, founded in 1581, was formerly in possession of what is now the imperial library, and contained also a valuable collection of Slavonic works which were carried off by the Swedes and ultimately dispersed. It was suppressed in 1853, and is now represented only by a theological faculty. The university of Graz, the capital of Styria, was founded in 1586, and is now one of the most flourishing centres, containing some 1200 students. The university of Salzburg, founded in 1623, was suppressed in 1810; that of Lemberg, founded in 1784 by the emperor Joseph II., was removed in 1805 to Cracow and united to that university. In 1816 it was opened on an independent basis. In the bombardment of the town in 1848 the university buildings were burnt down, and the site was changed to what was formerly a Jesuit convent. The fine library and natural history museum were at the same time

almost entirely destroyed. The university at the present time numbers over a thousand students. The most recent foundation is that of Czernowitz, founded in 1875, and numbering about 300 students. The universities of the Hungarian kingdom are three in number:—Budapest, originally founded at Tyrnau in 1635, now possessing four faculties—theology, jurisprudence, medicine, and philosophy (number of professors in 1885 180, students 3117); Kolozsvár (Klausenburg), now the chief Magyar centre, founded in 1872 and also comprising four faculties, but where mathematics and natural science supply the place of theology (number of professors in 1877 64, students 391); Zágráb (Agram), the Slavonian university, in Croatia, founded in 1869 but not opened until 1874, with three faculties, viz., jurisprudence, theology, and philosophy. The chief centre of Protestant education is the college at Debreczin, founded in 1531, which in past times was not unfrequently subsidized from England. It now numbers over 2000 students, and possesses a fine library.

Russia possesses, besides Dorpat (*supra*, p. 845), seven other universities. (1) Helsingfors, in Finland, was originally established by Queen Christina in Åbo (1640), and removed in 1826 to Helsingfors, where the original charter, signed by the celebrated Oxenstierna, is still preserved. It has four faculties, 38 professors, and 700 students. (2) Moscow is really the oldest Russian university, having been founded in 1755; it includes the faculties of history, physics, jurisprudence, and medicine; the professors are 69 in number, the students about 1660. (3) The university of St Vladimir at Kieff, originally founded at Vilna in 1803, was removed from thence to Kieff in 1833; the students number about 900, and the library contains 107,000 volumes. (4) Kazan (1804) includes the same faculties as Moscow; the students are about 450 in number, and it has a library containing 80,000 volumes. (5) Kharkoff (1804) numbers 600 students, and its library 55,000 volumes. (6) St Petersburg (1819) includes the four faculties of history, physics, jurisprudence, and Oriental languages, and numbers 1500 students. (7) Odessa, founded in 1865, represents the university of New Russia. Generally speaking, the universities of Russia are not frequented by the aristocratic classes; they are largely subsidized by the Government, and the annual fees payable by students are less than £7 a head. In 1863 the statutes of all the universities were remodelled; and since that time there has been a tendency to impress upon them a more national character, as distinguished from mere imitation of those in Germany.

The university of Athens (founded 22d May 1837) is modelled on the university systems of northern Germany, on a plan originally devised by Professor Brandis. It includes four faculties, viz., theology, jurisprudence, medicine, and philosophy. The professors (ordinary and extraordinary) are upwards of 60 in number, the students about 1500. There is also a school of pharmacy, chemistry, and anatomy, and a library of 130,000 volumes, with 800 manuscripts.

The history of the two English universities during the 16th and following centuries has presented, for the most part, features which contrast strongly with those of the Continental seats of learning. Both suffered severely from the confiscation of their lands and revenues during the period of the Reformation, but otherwise have generally enjoyed a remarkable immunity from the worst consequences of civil and political strife and actual warfare. Both long remained centres chiefly of theological teaching, but their intimate connexion at once with the state and with the Church of England, as "by law established," and the modifications introduced into their constitutions, prevented their becoming arenas of fierce polemical contentions like

those which distracted the Protestant universities of Germany.

The influence of the Renaissance, and the teaching of Erasmus, who resided for some time at both universities, exercised a notable effect alike at Oxford and at Cambridge. The names of Colet, Grocyn, and Linacre illustrate this influence at the former centre; those of Bishop Fisher, Sir John Cheke, and Sir Thomas Smith at the latter. The labours of Erasmus at Cambridge, as the author of a new Latin version of the New Testament, with the design of placing in the hands of students a text free from the errors of the Vulgate, were productive of important effects, and the university became a centre of Reformation doctrine some years before the writings of Luther became known in England. The foundation of Christ's College (1505) and St John's College (1511), through the influence of Fisher with the countess of Richmond, also materially aided the general progress of learning at Cambridge. The Royal Injunctions of 1535, embodying the views and designs of Thomas Cromwell, mark the downfall of the old scholastic methods of study at both universities; and the foundation of Trinity College, Cambridge, in 1546 (partly by an amalgamation of two older societies), represents the earliest conception of such an institution in England in complete independence of Roman Catholic traditions. Trinity (1554) and St John's (1555) at Oxford, on the other hand, founded during the reactionary reign of Mary, serve rather as examples of a transitional period.

In the reign of Elizabeth Cambridge became the centre of another great movement—that of the earlier Puritanism, St John's and Queens' being the strongholds of the party led by Cartwright, Walter Travers, and others. Whitaker, the eminent master of St John's, although he sympathized to some extent with these views, strove to keep their expression within limits compatible with conformity to the Church of England. But the movement continued to gather strength; and Emmanuel College, founded in 1584, owed much of its early prosperity to the fact that it was a known school of Puritan doctrine. Most of the Puritans objected to the discipline enforced by the university and ordinary college statutes—especially the wearing of the cap and the surplice and the conferring of degrees in divinity. The Anglican party, headed by such men as Whitgift and Bancroft, resorted in defence to a repressive policy, of which subscription to the Acts of Supremacy and Uniformity, and the Elizabethan statutes of 1570 (investing the "caput" with larger powers, and thereby creating a more oligarchical form of government), were the most notable results. Oxford, although the Puritans were there headed by Leicester, the chancellor, devised at the same time a similar scheme, the rigid discipline of which was further developed in the Laudian or Caroline statutes of 1636. It was under these respective codes—the Elizabethan statutes of 1570 and the Laudian statutes of 1636—that the two universities were governed until the introduction of the new codes of 1858. During the Commonwealth the Puritan occupation and administration, at either university, were accompanied by little injury to the colleges, and were far less prejudicial to learning than the Royalist writers of the Restoration would lead us to suppose. William Dell, who was master of Caius College from 1649 to 1660, advocated the formation of schools of higher instruction in the large towns, a proposal which was then looked upon as one of but faintly masked hostility to the older centres.

During the 17th century Cambridge became the centre of another movement, a reflex of the influence of the Cartesian philosophy, which attracted for a time considerable attention. Its leaders, known as the Cambridge

Platonists, among whom Henry More, Cudworth, and Whichcote were especially conspicuous, were men of high character and great learning, although too much under the influence of an ill-restrained enthusiasm and purely speculative doctrines. The spread of the Baconian philosophy, and the example of a succession of eminent scientific thinkers, among whom were Isaac Barrow, master of Trinity (1673-77), the two Lucasian professors, Isaac Newton (prof. 1669-1702) and his successor William Whiston (prof. 1702-11), and Roger Cotes (Plumian prof. 1707-16), began to render the exact sciences more and more an object of study, and the institution of the tripos examinations in the course of the first half of the 18th century established the reputation of Cambridge as a school of mathematical science. At Oxford, where no similar development took place, and where the statutable requirements with respect to study and exercises were suffered to fall into neglect, the degeneracy of the whole community as a school of academic culture is attested by evidence too emphatic to be gainsaid. The moral tone at both universities was at this time singularly low; and the rise of Methodism, as associated with the names of the two Wesleys and Whitefield at Oxford and that of Berridge at Cambridge, operated with greater effect upon the nation at large than on either of the two centres where it had its origin. With the advance of the present century, however, a perceptible change took place. The labours of Simeon at Cambridge, in connexion with the Evangelical party, and the far more celebrated movement known as Tractarianism, at Oxford, exercised considerable influence in developing a more thoughtful spirit at either university. At both centres, also, the range of studies was extended: written examinations took the place of the often merely formal *viva voce* ceremonies; at Cambridge classics were raised in 1824 to the dignity of a new tripos. The number of the students at both universities was largely augmented. Further schemes of improvement were put forward and discussed. And in 1850 it was decided by the Government to appoint commissioners to inquire what additional reforms might advantageously be introduced. Their recommendations were not all carried into effect, but the main results were as follows:—"The professoriate was considerably increased, reorganized, and re-endowed, by means of contributions from colleges. The colleges were emancipated from their mediæval statutes, were invested with new constitutions, and acquired new legislative powers. The fellowships were almost universally thrown open to merit, and the effect of this was not merely to provide ample rewards for the highest academical attainments, but to place the governing power within colleges in the hands of able men, likely to promote further improvements. The number and value of scholarships was largely augmented, and many, though not all, of the restrictions upon them were abolished. The great mass of vexatious and obsolete oaths was swept away; and, though candidates for the M.A. degree and persons elected to fellowships were still required to make the old subscriptions and declarations, it was enacted that no religious test should be imposed at matriculation or on taking a bachelor's degree."¹

In 1869 a statute was enacted at Cambridge admitting students as members of the university without making it imperative that they should be entered at any hall or college, but simply be resident either with their parents or in duly licensed lodgings.

The entire abolition of tests followed next. After several rejections in parliament it was eventually carried as a Government measure, and passed the House of Lords in 1871.

In 1877 the reports of two new commissions were followed by further changes, the chief features of which were the diversion of a certain proportion of the revenues of the colleges to the uses of the university, especially with a view to the encouragement of studies in natural science; the enforcement of general and uniform regulations with respect to the salaries, selection, and duties of professors, lecturers, and examiners; the abolition (with a few exceptions) of all clerical restrictions on headships or fellowships; and the limitation of fellowships to a uniform amount.

That these successive and fundamental changes have, on the whole, been in unison with the national wishes and in requirements may fairly be inferred from the remarkable increase in numbers during the last quarter of a century, and especially at Cambridge, where the number of undergraduates, which in 1862 was 1526, was in 1887 no less than 2979. In the academic year 1862-63 the number of matriculations was 448, and in 1886-87 1009.

Scarcely less influential, as a means of recovering for the two universities a truly national character, has been the work which both have been carrying on and aiding by the institution of local examinations and of university extension lectures. Of these two schemes, the former was initiated by both Oxford and Cambridge in the year 1858; the latter had its origin at Cambridge, having been suggested by the success attending a course of lectures to women delivered by Mr (now Professor) James Stuart, in 1867, in Liverpool, Manchester, Sheffield, and Leeds. By the former the standard of education throughout the country has been raised, both in public and in private schools. By the latter, instruction of the character and method which characterize university teaching has been brought within the reach of students of all classes and ages throughout the land.

So long ago as the year 1640 an endeavour had been made to bring about the foundation of a northern university for the benefit of the counties remote from Oxford and Cambridge. Manchester and York both petitioned to be made the seat of the new centre. Cromwell, however, rejected both petitions, and decided in favour of Durham. Here he founded the university of Durham (1657), endowing it with the sequestered revenues of the dean and chapter of the cathedral, and entitling the society "The Mentor or Provost, Fellows, and Scholars of the College of Durham, of the foundation of Oliver, &c." This scheme was cancelled at the Restoration, and not revived until the present century; but on the 4th July 1832 a bill for the foundation of a university at Durham received the royal assent, the dean and chapter being thereby empowered to appropriate an estate at South Shields for the establishment and maintenance of a university for the advancement of learning. The foundation was to be directly connected with the cathedral church, the bishop of the diocese being appointed visitor, and the dean and chapter governors; while the direct control was vested in a warden, a senate, and a convocation. A college, modelled on the plan of those at the older universities, and designated University College, Durham, was founded in 1837, Bishop Hatfield's Hall in 1846, and Bishop Cosin's Hall (which no longer exists) in 1851. The university includes all the faculties, and in 1865 there was added to the faculty of arts a school of physical science, including pure and applied mathematics, chemistry, geology, mining, engineering, &c. In 1871 the corporation of the university, in conjunction with some of the leading landed proprietors in the adjacent counties, gave further extension to this design by the foundation of a college of physical science at Newcastle-upon-Tyne, designed to teach scientific principles in their application to engineering, mining, manufactures, and agriculture.

¹ Brodrick, *University of Oxford*, pp. 136, 137.

Students who had passed the required examinations were made admissible as associates in physical science of the university. There is also a medical college which stands in similar relations to Durham, of which university Codrington College, Barbados, and Fourah Bay College, Sierra Leone, are likewise affiliated colleges.

University of London. The university of London had its origin in a movement initiated in the year 1825 by Thomas Campbell, the poet, in conjunction with Henry (afterwards Lord) Brougham, Mr (afterwards Sir) Isaac Lyon Goldsmid, Joseph Hume, and some influential Dissenters, most of them connected with the congregation of Dr Cox of Hackney. The scheme was originally suggested by the fact that Dissenters were practically excluded from the older universities; but the conception, as it took shape, was distinctly non-theological. The first council, appointed December 1825, comprised names representative of nearly all the religious denominations, including (besides those above mentioned) Zachary Macaulay, George Grote, James Mill, William Tooke, Lord Dudley and Ward, Dr Olinthus Gregory, Lord Lansdowne, Lord John Russell, and the duke of Norfolk. On 11th February 1826 the deed of settlement was drawn up; and in the course of the year seven acres, constituting the site of University College, were purchased, the foundation stone of the new buildings being laid by the duke of Sussex 30th April 1827. The course of instruction was designed to include "languages, mathematics, physics, the mental and the moral sciences, together with the laws of England, history, and political economy, and the various branches of knowledge which are the objects of medical education." In October 1828 the college was opened as the university of London. But in the meantime a certain section of the supporters of the movement, while satisfied as to the essential soundness of the primary design as a development of national education, entertained considerable scruples as to the propriety of altogether dissociating such an institution from the national church. This feeling found expression in the foundation and incorporation of King's College (14th August 1829), opened 8th October 1831, and designed to combine with the original plan instruction in "the doctrines and duties of Christianity, as the same are inculcated by the United Church of England and Ireland." This new phase of the movement was so far successful that in 1836 it was deemed expedient to dissociate the university of London from University College as a "teaching body," and to limit its action simply to the institution of examinations and the conferring of degrees,—the college itself receiving a new charter, and being thenceforth designated as University College, London, while the rival institution was also incorporated with the university, and was thenceforth known as King's College, London. In the charter now given to the university it was stated that the king "deems it to be the duty of his royal office to hold forth to all classes and denominations of his faithful subjects, without any distinction whatsoever, an encouragement for pursuing a regular and liberal course of education." The charters of the university of London and of University College, London, were signed on the same day, 28th November 1836. In 1869 both the colleges gave their adhesion to the movement for the higher education of women which had been initiated elsewhere, and in 1880 ladies were for the first time admitted to degrees.

Victoria. The Victoria University took its origin in the institution known as the Owens College, Manchester,—so called after a wealthy citizen of that name to whom it owed its foundation. The college was founded 12th March 1851, for the purpose of affording to students who were unable, on the ground of expense, to resort to Oxford or Cambridge an education of an equally high class with that given at those

centres. The institution was, from the first, unsectarian in character. In July 1877 a memorial was presented to the privy council praying for the grant of a charter to the college, conferring on it the rank of a university, to be called the "university of Manchester." The localization implied in this title having met with opposition from the Yorkshire College at Leeds, it was resolved that the university should be called the "Victoria University." Under this name the foundation received its charter 20th April 1880. "The characteristic features of the Victoria University, as compared with other British universities, are these:—(a) it does not, like London, confer its degrees on candidates who have passed certain examinations only, but it also requires attendance on prescribed courses of academic study in a college of the university; (b) the constitution of the university contemplates its (ultimately) becoming a federation of colleges; but these colleges will not be situated, like those of Oxford and Cambridge, in one town, but wherever a college of adequate efficiency and stability shall have arisen. University College, Liverpool, and the Yorkshire College, Leeds, having fulfilled these requirements, have become affiliated with the university. The university, like the older bodies in England and Scotland, is at once a teaching and an examining body, and there is an intimate *rapport* between the teaching and the examining functions. To give it a general or national character, the governing body consists partly of persons nominated by the crown and partly of representatives of the governing and teaching bodies of the colleges and of the graduates of the university. External examiners are appointed, who conduct the examinations in conjunction with examiners representing the teaching body. The graduates of the university meet its teachers in convocation to discuss the affairs of the university. Convocation will elect future chancellors, and a certain number of representatives on the court" (Thompson, *The Owens College, &c.*, p. 548). Like the Johns Hopkins University in America, the Victoria University has instituted certain fellowships (styled the Berkeley fellowships) for the encouragement of research.

In Scotland the chief change to be noted in connexion with the university of St Andrews is the appropriation in 1579 of the two colleges of St Salvator and St Leonard to the faculty of philosophy, and that of St Mary to theology. In 1747 an Act of Parliament was obtained for the union of the two former colleges into one. Glasgow, in the year 1577, received a new charter, and its history from that date down to the Restoration was one of almost continuous progress. The restoration of Episcopacy, however, involved the alienation of a considerable portion of its revenues, and the consequent suspension of several of its chairs. In 1864 the old university buildings were sold and, a Government grant having been obtained, together with private subscriptions, the present new buildings were erected from the joint fund. The faculties now recognized at Glasgow are those of arts, theology, jurisprudence, and medicine. At Aberdeen an amalgamation, similar to that at St Andrews, took place, by virtue of the Universities Act of 1858, of the two universities of King's College and Marischal College. In conjunction with Glasgow, this university returns a member to parliament. The peculiar constitution of the college at Edinburgh, as defined by its charter (the government being vested entirely in the lord provost, magistrates, and council, as patrons and guardians), involved the senate in frequent collisions with the town council. The latter, being a strictly representative body, included elements with which the senate of the university sometimes found it difficult to work harmoniously, and its disposition to dictate was strongly resented by the distinguished metaphysician and professor Sir William Hamilton. On the other hand, the council sometimes

Changes in universities of St Andrews, Glasgow, and Aberdeen.

Changes in university of Edinburgh.

exercised a beneficial discretion by appointing professors of ability whom the senate might have regarded as ineligible on the ground of their religious tenets. The Disruption of 1843 emancipated the lay professors from subscription to the Established Church of Scotland, and resulted in many of the important changes which were subsequently introduced in the Universities Act of 1858. On the 28th October 1859 the town council, notwithstanding that their powers were already terminated by the provisions of the Act, availed themselves of a technical right to appoint a principal,—their choice falling upon Sir David Brewster. The great landmark in the history of the Scottish as in that of the English universities is represented by the remodeling of the several constitutions of these bodies in the year 1858. The commissioners of 1858–62 left the university of Edinburgh in the possession of constitutional autonomy, with its studies and degrees regulated by ordinances. The students also received the rectorial franchise, but were not, as at Glasgow and Aberdeen, divided into nations. In arts the B.A. degree was abolished, the M.A. representing the only degree in this faculty, as at the other Scottish universities. The course of study was divided into three departments:—(1) classics; (2) mathematics, including natural philosophy; (3) mental science and English literature. In each department it was required that there should be an additional examiner besides the professor, so that the candidates should not be entirely examined by their own teachers. It was also provided that, instead of one examination for the degree at the end of a student's course, examinations in each of the departments might be passed separately. In the twenty years beginning with 1863, 1400 M.A. degrees have been conferred, as against 250 in the twenty years preceding. In the faculty of medicine, the original single degree of doctor of medicine gave place to three classes—bachelor of medicine (M.B.), master in surgery (C.M.), and doctor of medicine (M.D.). In 1866 it was further laid down that theses should no longer be demanded from candidates for the lower degrees of M.B. and C.M., and, on the other hand, that the degree of M.D. should not be conferred on persons not showing any evidence of medical study after leaving the university, but that a thesis should be invariably required. Since the enactment of these ordinances the number of the medical students has increased from about 500 to over 1700. In the faculty of law the title of the degree was to be LL.B., and it was to be conferred only on those who had already graduated as M.A. But the minor degree, that of "bachelor of law" (B.L.), might be conferred if the candidate had attended one course of lectures in the faculty of arts, and passed a preliminary examination in (1) Latin, (2) Greek, French or German, and (3) any two of the three subjects—logic, moral philosophy, and mathematics. The chair of public law, which had fallen into abeyance in 1832, was reconstituted, and the chair of universal civil history was converted into a professorship of history and constitutional law. The degree of doctor of laws was left, as before, a purely honorary degree. Chairs of Sanskrit, engineering, geology, commercial and political economy, education, fine art, and the Celtic languages have also been founded. By the Representation of the People (Scotland) Act, 1868, the universities of Edinburgh and St Andrews were empowered to return jointly a member to the House of Commons.

Parliamentary grants to Scottish universities. A parliamentary return for the ten years ending 30th March 1883 showed that the sums voted annually by parliament or chargeable on the consolidated fund to the four universities had amounted during that period to £65,821 for Aberdeen, £85,906 for Edinburgh, £66,182 for Glasgow, and £38,111 for St Andrews. In addition to these sums Edinburgh had received £80,000 and Glasgow £20,000 in the form of special grants in aid.

Trinity College, Dublin, was founded in 1591, under the auspices of Sir John Perrot, the Irish viceroy. A royal charter nominated a provost and a minimum number of three fellows and three scholars as a body corporate, empowered to establish among themselves "whatever laws of either of the universities of Cambridge or Oxford they may judge to be apt and suitable; and especially that no other persons should teach or profess the liberal arts in Ireland without the queen's special licence." The first five provosts of Trinity College were all Cambridge men, and under the influence of Archbishop Loftus, the first provost, and his successors, the foundation received a strongly Puritan bias. Prior to the year 1873 the provostship, fellowships, and foundation scholarships could be held only by members of the Church of Ireland; but all such restrictions were abolished by Act 36 Vict. c. 21, whereby the requirement of subscription to any article or formulary of faith was finally abrogated. As at present constituted, the ordinary government is in the hands of the provost and senior fellows in conjunction with the visitors and council,—the supreme authority being the crown, except so far as limited by Act of Parliament.

The first departure in Ireland from the exclusive system of education formerly represented by the foundation at Dublin, dates from the creation of the Queen's University, incorporated by royal charter 3d September 1850. By this charter the general legislation of the university, together with its government and administration, was vested in the university senate. In 1864 the charter of 1850 was superseded by a supplementary charter, and the university reconstituted "in order to render more complete and satisfactory the courses of education to be followed by students in the colleges"; and finally, in 1880, by virtue of the Act of Parliament known as the University Education (Ireland) Act, 1879, the Queen's University gave place to the Royal University of Ireland, which was practically a reconstitution of the former foundation, the dissolution of the Queen's University being decreed so soon as the newly constituted body should be in a position to confer degrees; at the same time all graduates of the Queen's University were recognized as graduates of the new university with corresponding degrees, and all matriculated students of the former as entitled to the same status in the latter. The university confers degrees in arts (B.A., M.A., D.Litt.), science, engineering, music, medicine, surgery, obstetrics, and law. The preliminary pass examinations in arts are held at annually selected centres,—those chosen in 1885 being Dublin, Belfast, Carlow, Cork, Galway, Limerick, and Londonderry. All honour examinations and all examinations in other faculties are held in Dublin. The Queen's Colleges at Belfast, Cork, and Galway were founded in December 1845, under an Act of Parliament "to enable Her Majesty to endow new colleges for the advancement of learning in Ireland," and were subsequently incorporated as colleges of the university. Their professors were at the same time constituted professors in the university, and conducted the examinations. But in the reconstruction of 1880 the chief share in the conduct of the examinations and advising the senate with respect to them was vested in a board of fellows, elected by the senate in equal numbers from the non-denominational colleges and the purely Catholic institutions. The colleges retain, however, their independence, being in no way subject to the control of the university senate except in the regulations with respect to the requirements for degrees and other academic distinctions. On the other hand, the obligation formerly imposed of a preliminary course of study at one or other of the colleges before admission to degrees was abolished at the foundation of the Royal University, the examinations being now open, like those of the university

Colleges at Belfast, Cork, and Galway.

of London, to all matriculated students on payment of certain fees.

Colleges in Wales:—
St David's, Lampeter, possesses the right of conferring degrees. It was founded in 1822 for the purpose of educating clergymen in the principles of the Established Church of England and Wales, mainly for the supply of the Welsh dioceses. The number of the professors in 1887 was 8, and the number of the students 120. The next college in order of foundation is Aberystwith. It was founded 9th October 1872, but possesses no charter, and is mainly supported by the Dissenting bodies. The staff of professors numbers 13, and the students number 150. The University College of South Wales and Monmouthshire at Cardiff was founded in 1883. The number of professors in 1887 was 9, lecturers 4, demonstrators 2; number of students 140. The University College of North Wales at Bangor received its charter 4th June 1885, its object being to "provide instruction in all the branches of a liberal education except theology." Its staff consists of a principal, 8 professors or lecturers, and 2 demonstrators; the number of the students is 127. There is also a hall of residence for women students. At each of these three last-named colleges students proceeding to degrees have to go through either a London, Edinburgh, Glasgow, or Dublin course of study, but at Edinburgh, Glasgow, and Dublin a certain proportion of the term of residence ordinarily required is remitted in their favour.

Calcutta. In India, the three older universities all date from 1857,—that of Calcutta having been incorporated January 24, Bombay July 18, Madras September 5, in that year. At these three universities the instruction is mainly in English. "A university in India is a body for examining candidates for degrees, and for conferring degrees. It has the power of prescribing text-books, standards of instruction, and rules of procedure, but is not an institution for teaching. Its governance and management are vested in a body of fellows, some of whom are *ex officio*, being the chief European functionaries of the state. The remainder are appointed by the Government, being generally chosen as representative men in respect of eminent learning, scientific attainment, official position, social status, or personal worth. Being a mixed body of Europeans and natives, they thus comprise all that is best and wisest in that division of the empire to which the university belongs, and fairly represent most of the phases of thought and philosophic tendencies observable in the country. The fellows in their corporate capacity form the senate. The affairs of the university are conducted by the syndicate, consisting of a limited number of members elected from among the fellows. The faculties comprise arts and philosophy, law, medicine, and civil engineering. A degree in natural and physical science has more recently been added" (Sir R. Temple, *India in 1880*, p. 145). The Punjab university was incorporated in 1883,—the Punjab University College, prior to that date, having conferred titles only and not degrees. The main object of this university is the encouragement of the study of the Oriental languages and literature, and the rendering accessible to native students the results of European scientific teaching through the medium of their own vernacular. The Oriental faculty is here the oldest, and the degree of B.O.L. (bachelor of Oriental literature) is given as the result of its examinations. At the Oriental College the instruction is given wholly in the native languages. In 1887 the senate at Cambridge (mainly on the representations of Mr C. P. Ilbert, formerly vice-chancellor of the university of Calcutta) adopted resolutions whereby some forty-nine collegiate institutions already affiliated to the latter body were affiliated to the university of Cambridge, their students thus becoming entitled to the remission of one year in the ordinary statutable requirements with respect to residence at Cambridge. It is at these institutions, and the colleges of the first or second grade in the other presidencies, that the instruction is given.

Sydney. In Australia, the university of Sydney was incorporated by an Act of the colonial legislature which received the royal assent 9th December 1851, and on 27th February 1858 a royal charter was granted conferring on graduates of the university the same rank, style, and precedence as are enjoyed by graduates of universities within the United Kingdom. Sydney is also one of the institutions associated with the university of London from which certificates of having received a due course of instruction may be received with

a view to admission to degrees. There are four faculties, viz., arts, law, medicine, and science. The design of the university is to supply the means of a liberal education to all orders and denominations, without any distinction whatever. An Act for the purpose of facilitating the erection of colleges in connexion with different religious bodies was, however, passed by the legislature during the session of 1884, and since that time colleges representing the Episcopalian, Presbyterian, and Roman Catholic Churches have been founded. In 1885 the total number of students attending lectures in the university was 206. The university of Melbourne, Mel-bourne, in the colony of Victoria, was incorporated and endowed by royal Act 22d January 1853. This Act was amended 7th June 1881. Here also no religious tests are imposed on admission to any degree or election to any office. The council is empowered, after due examination, to confer degrees in all the faculties (excepting divinity) which can be conferred in any university within the British dominions. It is also authorized to affiliate colleges; and Trinity College (Church of England) was accordingly founded in 1870 and Ormond College (Presbyterian) in 1879. The founding of a university for Queensland is at the present time in contemplation. The university of Adelaide in South Australia (founded mainly Adelaide, by the exertions and munificence of Sir Walter Watson Hughes) was incorporated by an Act of the colonial legislature in 1874, in which year it was further endowed by Sir Thomas Elder. In 1881 letters patent were granted by the English crown whereby degrees conferred by the university were constituted of equal validity with those of any university of the United Kingdom. The faculties in the university are those of arts, medicine, law, science, and music. The number of matriculations since the foundation amounted in 1886 to 284, the number of undergraduates in that year being 90.

The university of New Zealand, founded in 1870, and reconstituted New Zealand, in 1874 and 1875, is empowered by royal charter to grant the several degrees of bachelor and master of arts, and bachelor and doctor in law, medicine, and music. Women are admitted to degrees. To this the Auckland University College, Nelson College, Canterbury College, and the university of Otago stand in the relation of affiliated institutions. This last-named institution was Otago, founded in 1869 by an order of the provincial council, with the power of conferring degrees in arts, medicine, and law, and received as an endowment 100,000 acres of pastoral land. It was opened in 1871 with a staff of three professors, all in the faculty of arts. In 1872 the provincial council further subsidized it by a grant of a second 100,000 acres of land, and the university was now enabled to make considerable additions to the staff of professors and lecturers, to establish a lectureship in law, and to lay the foundations of a medical school. In 1874 an agreement was made between the university of New Zealand and that of Otago, whereby the functions of the former were restricted to the examination of candidates for matriculation, for scholarships, and for degrees; while the latter bound itself to become affiliated to the university of New Zealand, to hold in abeyance its power of granting degrees, and to waive the claim which it had advanced to a royal charter. As the result of this arrangement, the university of Otago became possessed of 10,000 acres of land which had been set apart for university purposes in the former province of Southland. In 1877 a school of mines was established in connexion with the university.

In Canada the McGill College and University at Montreal was Montreal, founded by royal charter in 1821 (amended in 1852) on the foundation of the Honourable James McGill, who died at Montreal 19th December 1813. A number of colleges and schools throughout the province stand in the relation of affiliated institutions. The university is Protestant but undenominational. It includes the faculties of arts, applied sciences, medicine, and law. In 1885 the total number of students, including women, was 526. The university of Toronto was originally established by royal charter in 1827, under the title of King's College, with certain religious restrictions, resembling those at that time in force at the English universities, but in 1854 these restrictions were abolished, and in 1849 the designation of the university was changed into that of the university of Toronto. In 1873 further amendments were made in the constitution of the university. The chancellor was made elective for a period of three years by convocation, which was at the same time reorganized so as to include all graduates in law, medicine, and surgery, all masters of arts, and bachelors of arts of three years standing, all doctors of science, and bachelors of science of three years standing. The powers of the senate were also extended to all branches of literature, science, and the arts, to granting certificates of proficiency to women, and to affiliating colleges. The work of instruction is performed by University College, which is maintained out of the endowment of the provincial university, and governed by a council composed of the residents and the professors. Its several chairs include classical literature, logic and rhetoric, mathematics and natural philosophy, chemistry and experimental philosophy, history and English literature, mineralogy and geology, metaphysics and ethics, meteorology and natural history, and lectureships on Oriental literature, German, and French. Other universities and colleges with power to confer

degrees are the Victoria University at Cobourg (1836), supported by the Methodist Church of Canada; Queen's University, Kingston (1841), representing the Presbyterian body; and the university of Trinity College, Toronto, founded in 1851 on the suppression of the faculty of divinity in King's College. Lennoxville is a centre for university instruction in conformity with Church of England principles.

In Africa, an Act for the incorporation of the university of the Cape of Good Hope received the royal assent 26th June 1873, the council being empowered to grant degrees in arts, law, and medicine.

In the United States of America university education has received a great extension, without, however, exercising in Europe that reflex influence discernible in so many other relations. The report of the commissioners of education for 1883-84 gives a list of no less than 370 degree-giving universities or colleges; but of these a large proportion are sectarian, others represent only a single faculty, and nearly nine-tenths have been founded within the last thirty-five years. Although a higher education has unquestionably been thus very widely diffused, the undue multiplication of centres has, in some provinces, lowered the standard of attainment and led to a consequent depreciation in the value of university degrees. This tendency it was sought to counteract in the State of Ohio, some twenty-five years ago, by an organization of the different colleges. The instruction given is, in most cases, almost gratuitous, the charge to each student being less than 30 dollars a year. This cheapening of a higher education is not, however, attended with quite the same results as in Germany (where lads with little aptitude for a professional career are thus attracted to the professions), the rapidly increasing population and the wider scope for mechanical or agricultural pursuits probably exercising a beneficial counteracting influence. The distinguishing characteristics which belong to these numerous centres are described by the president of the Johns Hopkins University, in an address delivered at Harvard in 1886, as suggestive of four different classes of colleges,—(1) those which proceed from the original historic colleges, (2) those established in the name of the State, (3) those avowedly ecclesiastical, (4) those founded

by private benefactions. To the first class belong Harvard College and Yale College with their offshoots. Of these two, the former was founded in 1638 at Cambridge, Massachusetts, by a former fellow of Emmanuel College at Cambridge in England, and represented the Puritan tenets for which the parent society was at that time noted; the latter was founded in 1701 by the combined action of a few of the ministers of the State, a charter being given in the same year by the colonial legislature. It was for a long time chiefly supported by the Congregationalists, but is now unsectarian. The total number of students at Harvard in 1882 was 988, at Yale 692. The university of Pennsylvania was founded in 1751 by Thomas Penn and Richard Penn, on the lines of a scheme drawn up by Benjamin Franklin, and was from the first placed on a basis comprising all denominations. It is distinguished by the liberality with which it has opened its courses of instruction to the inhabitants of the city generally; the degree of Ph.D. is conferred on all comers after due examination. At Haverford and Lafayette Colleges, and also at the Lehigh university, "advanced degrees" are offered "only for higher study, prolonged beyond the collegiate course," instead of being conferred as a matter of routine after a certain term of years. The Johns Hopkins University, also an unsectarian body, was founded at Baltimore in 1867, and is already a school of established reputation, and especially resorted to by those designing to follow the profession of teachers. It is also distinguished by the possession of fellowships, to be held only by students intending to pursue some especial line of original research. Other steadily growing centres are Columbia College in New York, founded in 1754; the Cornell University, also unsectarian, recently enriched by the acquisition of a considerable endowment; Brown's University in Providence; and those of Princeton, Michigan, Virginia, and California. At Amherst College, where the number of students in 1882 was 339, the experiment has recently been made of partially dispensing with examinations during the course of

study, where the students give evidence of having made satisfactory progress. Considerable modifications have also taken place in the courses of study, nearly all the colleges having now adopted the system of "parallel courses," and the principle of selection between these. Female education has received in America an extension which it has attained in no other country, and one of the colleges (that of Wellesley) numbers several hundred students. Since the war of 1861 a greatly increased attention has been given throughout the universities to physical training and athletic exercises, and excellent gymnasia, constructed on German models, have been erected.

The accompanying table (p. 857), prepared by the council of education for the year 1883-84, shows the distribution of these centres in the different States, together with their numbers, revenues, libraries, and the estimated value of their endowments.

Authorities.—On the earlier history and organization of the mediæval universities, the student should consult F. C. von Savigny, *Gesch. d. römischen Rechts im Mittelalter*, 7 vols., 1826-51; for the university of Paris, Du Boulay, *Historia Universitatis Parisiensis*, 6 vols., Paris, 1665; Crevier, *Hist. de l'Université de Paris*, 7 vols., Paris, 1761, and C. Jourdain, *Hist. de l'Université de Paris au XVII^{me} et au XVIII^{me} Siècle*, Paris, 1802; of these the work of Du Boulay (Bulæus) is one of great research and labour, but wanting in critical judgment, while that of Crevier is little more than a readable outline drawn from the former. The views of Du Boulay have been challenged on many important points by P. H. Denife in the first volume of his *Die Universitäten des Mittelalters bis 1400* (1885), and more particularly on those relating to the organization of the early universi-

ties. The work of Meiners, *Gesch. d. Entstehung u. Entwicklung der hohen Schulen unsers Erdtheils*, 4 vols. (1802-5), must be regarded as almost superseded as a general history, and the same may be said of Huber's work on the English universities, *Die englischen Universitäten* (Cassel, 1839-40), translated by F. W. Newman, 3 vols. (1845). Much useful criticism on both the English and the Continental universities will be found in Sir W. Hamilton's *Discussions*, &c., 1853. For the German universities, the works of Zarncke, *Die deutschen Universitäten im Mittelalter* (Leipzig, 1857), and Paulsen, *Gesch. d. gelehrten Unterrichts auf den deutschen Schulen und Universitäten* (Leipzig, 1885), will be found the most trustworthy, the former for the mediæval, the latter for the modern period. To these may be added two articles by Paulsen in vol. xiv. of Von Sybel's *Historische Zeitschrift*:—(1) "Gründung" and (2) "Organisation u. Lebensordnungen d. deutschen Universitäten im Mittelalter"; Tholuck, *Das akademische Leben des 17. Jahrhunderts*, 2 vols. (Halle, 1853-54); Von Raumer, *Gesch. d. Pädagogik*, vol. iv. (4th ed., 1872); Dolch, *Gesch. d. deutschen Studententhums* (1858); Sybel, *Die deutschen Universitäten* (2d ed., 1874); and Dr J. Conrad, *The German Universities for the last Fifty Years*, translated by Hutchinson, with preface by James Bryce, M.P. (Glasgow, 1885). For Oxford, there are the laborious collections by Anthony Wood, *History and Antiquities of the University and of the Colleges and Halls of Oxford*, edited with continuation by Rev. J. Gutch, 5 vols. (1786-96), and *Athenæ and Fasti Oxonienses*, edited by Dr P. Bliss, 4 vols. (1813-20); also the publications of the Oxford Historical Society; *A History of the University of Oxford from the Earliest Times to 1530*, by H. C. Maxwell Lyte (1886); and *Statutes of the University of Oxford compiled in 1536 under Authority of Archbishop Layard*, ed. Griffiths (Oxford, 1888). For Cambridge, the researches of C. H. Cooper, greatly surpassing those of Wood in thoroughness and impartiality, are comprised in three series: (1) *Annals of Cambridge*, 4 vols. (1842-52); (2) *Athenæ Cantabrigienses, 1500-1600*, 2 vols. (1855-61); (3) *Memorials of Cambridge*, 3 vols. (new ed., 1884). The *Archæological History of the University of Cambridge and of the Colleges*, by the late Robert Willis, edited and continued by J. Willis Clark, 4 vols. (1886), is a work of admirable thoroughness and completeness. To these may be added *Cambridge in the Seventeenth Century*; *Lives of Nicholas Ferrar and Matthew Robinson*, by Prof. John E. B. Mayor, 2 vols. (1855, 1856); and Baker's *History of the College of St John the Evangelist, Cambridge*, edited by Mayor, 2 vols. (1869); also J. B. Mullinger, *History of the University of Cambridge from the Earliest Times to Accession of Charles I.*, 2 vols. (1873-85). For both universities see the *Documents* issued by the Oxford and Cambridge Commissions of 1858; also the Wood, Earne, Tanner, and Rawlinson MSS., and the Cottonian, Harleian, Lansdowne (especially Kennett and Strype), Baker, and Cole collections. (J. B. M.)

UNTERWALDEN is one of the Forest cantons of Switzerland, ranking as sixth in the Confederation. It is composed of two valleys through which run two streams both called the Aa, and which are called Obwald and Nidwald from their position with regard to the great forest of the Kernwald in which they are situated. In old documents the inhabitants are always described as "homines intramontani," whether "vallis superioris" (Obwald) or "vallis inferioris" (Nidwald). The total area of Obwald is 183.3 square miles, 154.2 of which are classed as productive (forests 37.6), while of the remainder 3.8 are covered by glaciers and 4.3 by lakes. The area of Nidwald is 112.1 square miles, 84.1 being productive (forests 27.7); of the rest the cantonal bit of the Lake of Lucerne covers 12.8. The highest point in the canton is the Titlis (10,627 feet) in Obwald.

The census of 1880 returned the population of Obwald as 15,356, an increase of 941 on 1870, and that of Nidwald as 11,992, an increase of 291. In both the women have a small majority over the men. The native tongue of practically the whole population is German (15,254 in Obwald, 11,869 in Nidwald), and they are nearly all Roman Catholics (15,078 in Obwald, 11,901 in

Nidwald). Till 1814 the canton was in the diocese of Constance; since that time it has (like Uri) formed legally part of no diocese, though it is provisionally administered by the bishop of Chur. The capital of Obwald is Sarnen (4039 inhabitants), Kerns (2500) being the only other place which is more than a village; that of Nidwald is Stanz (2210). The population is purely agricultural and pastoral. In Obwald the forests are remarkable, in Nidwald the fiery energy of the inhabitants. In educational matters the standard is not very high, but is being gradually raised. At the head of the Nidwald valley (but legally in Obwald) stands the great Benedictine monastery of Engelberg, founded in 1121. There are no railways, but one is being made from Lucerne through Obwald over the Brünig Pass to Meyringen in Bern.

Historically Obwald was part of the Aargau, and Nidwald of the Zürichgau. In both there were many great landowners (especially the abbey of Murbach and the Hapsburgs) and few free men; while the fact that the Hapsburgs were counts of the Aargau and the Zürichgau further delayed the development of political freedom. Both took part in the risings of 1245-47, and in 1248 Sarnen was threatened by the pope with excommunication for opposing its hereditary lord, the count of Hapsburg. The alleged cruelties committed by the Hapsburgs do not, however, appear in history till

Justinger's *Chronicle*, 1420 (see TELL). On April 16, 1291, Rudolph the future emperor bought from Murbach all its estates in Unterwalden and thus ruled this district as the chief landowner, as count, and as emperor. On 1st August 1291 Nidwald formed the "Everlasting League" with Uri and Schwyz (this being the first known case in which its common seal is used), Obwald joining a little later on. In 1304 the two valleys were joined together under the same imperial bailiff, and in 1309 Henry VII. confirmed to them all the liberties granted by his predecessor—though none are known to have been granted. However, this placed Unterwalden on an equal political footing with Uri and Schwyz; and as such it took part in Morgarten fight (also driving back an invasion over the Brünig Pass) and in the renewal of the Everlasting League at Brunnen (1315), as well as at Sempach (1386), and in driving back the Gugler or English freebooters (1375). For physical reasons, it was difficult for Unterwalden to enlarge its territories. Yet in 1368 it acquired Alpnach, and in 1378 Hergiswyl. So too Obwald shared with Uri in the conquest of the Val Leventina (1403), and in the purchase of Bellinzona (1419), as well as in the loss of both (1426). It was Nidwald that, with Schwyz and Uri, finally won (1500) and ruled (till 1798) Bellinzona, Riviera, and Val Blegno; while both shared in conquests of Aargau (1415), Thurgau (1460), and Locarno, &c. (1512), and in the temporary occupation of the Val d'Ossola (1410-14 to 1417-22). In the Burgundian war Unterwalden, like the other Forest cantons, long hung back through jealousy of Bern, but came to the rescue in time of need. In 1481 it was at Stanz that the Confederates nearly broke up the League for various reasons, and it was only by the intervention then of the holy hermit Nicholas von der Flüe (of Sachseln in Obwald) that peace was restored, and the great federal agreement known as the compact of Stanz concluded. Like the other Forest cantons, Unterwalden clung to the old faith at the time of the Reformation, being a member of the "Christliche Vereinigung" (1529) and of the Golden League (1586).

In 1798 Unterwalden resisted the Helvetic republic, but, having formed part of the short-lived Tellgau, became a district of the canton of the Waldstätten. Obwald submitted at an early date, but Nidwald, refusing to accept the oath of fidelity to the constitution mainly on religious grounds, rose in desperate revolt (September 1798), and was only put down by the arrival of 15,000 armed men and by the storming of Stanz. In 1803 its independence as a canton was restored, but in 1815 Nidwald refused to accept the new constitution, and federal troops had to be employed to put down its resistance, the punishment inflicted being the transfer to Obwald of the jurisdiction over the abbey lands of Engelberg (since 1421 "protected" by both valleys), which in 1798 had fallen to the lot of Nidwald. Since that time the history of Unterwalden has been like that of the other Forest cantons. It was a member of the "League of Sarnen" (1832), to oppose the reforming wishes of other cantons, and of the "Sonderbund" (1848); it was defeated in the war of 1847; and it voted against the acceptance of the federal constitution both in 1848 and in 1874. It forms at present two half cantons, each sending one representative to the federal "assembly of states." In local matters the two valleys are independent. In each the supreme authority is the "landsgemeinde" (meeting on the last Sunday in April), composed of all male citizens of twenty (Obwald) or eighteen (Nidwald) years of age, while the cantonal council, which drafts measures and sanctions the expenditure of sums below certain fixed small amounts, is composed in Obwald of 80 members (including the executive council) elected by the people for 4 years, and in Nidwald of 48 (besides the executive council) chosen in the same way for 6 years. The executive council is in both cases elected by the "landsgemeinde"; in Obwald it consists of 3 officials and 4 ordinary members, and in Nidwald of 6 officials and 5 ordinary members,—the official members being chosen every year, the ordinary every 4 or 3 years respectively. The existing constitution of Obwald is that of 1867; that of Nidwald is dated 1850, and was amended in 1877-78.

It is very remarkable that in both valleys the old "common lands" are still in the hands of the old guilds, and "gemeinden" consist of natives, not merely residents, though in Obwald these contribute to the expenses of the new "political communes" of residents, while in Nidwald the latter have to raise special taxes. In Engelberg (which still retains some independence) the poor are greatly favoured in the division of the common lands and their proceeds, and unmarried persons (or widowers and widows) receive only half the share of those who are married.

See J. Businger, *Die Geschichten des Volkes von Unterwalden*, 2 vols., 1827-28.

UNYORO, a kingdom of Central Africa, bounded on the N. and E. by the Nile, on the W. by the Albert Nyanza, and on the S.E. by the kingdom of Uganda. Its area is about 1600 square miles. The country is very fertile, well-watered, and thickly wooded; for the most part it is hilly in character, especially on the borders of the Albert Lake and in the neighbourhood of Massindi and

Kiroto, where the mountains have an altitude of from 5000 to 6000 feet. The population is about 1,500,000. The Wanyoro are of a dark reddish-brown colour, and are fully clothed, but are not so fine in physique, nor so high in intellectual development as their neighbours the Waganda, to whom, however, they appear to be very nearly related. The reigning family in Unyoro belongs to the Wahuma tribe, and is probably the oldest reigning Wahuma family in this part of Africa. The country is governed on the feudal system. Numerous tribes to the east and north of the Nile, and also on the western side of the Albert Nyanza, pay a small tribute to the Wanyoro. The latter possess large herds of cattle, and are very good herdsmen. The land, too, is cultivated to a considerable extent,—bananas, sweet potatoes, and dhurra being grown in large quantities. Coffee and tobacco are cultivated to a small extent. The people are very superstitious, and the numerous medicine men and women reap a rich harvest from their credulity. The Wanyoro huts are dome-shaped, small, and extremely filthy and full of vermin, although the people themselves are cleanly. Polygamy is universal, even the poorest man possessing two or three wives. Notwithstanding this, the people are fairly moral; but Unyoro is remarkable amongst Central African tribes for the existence of a definite class of courtesans. The Wanyoro are moderately skilful workmen, and their iron-work, pottery, and wood-work are both neat and tasteful. The only article they export is salt, which is obtained in considerable quantities at Kibiro on the shores of Lake Albert.

See Baker's *Albert Nyanza*, Felkin and Wilson's *Uganda and the Egyptian Soudan*, and various papers in *Petermann's Mittheilungen* by Emin Pasha.

UPANISHADS. See SANSKRIT, vol. xxi. p. 280, and BRAHMANISM.

UPAS, a Javanese word meaning poison, and specially applied by the Malays and people of western Java to the poison derived from the gum of the anchar tree (*Antiaris toxicaria*), one of the *Artocarpeæ*, which was commonly used in Celebes to envenom the bamboo darts of the natives. The name of the upas tree has become famous from the mendacious account (professedly by one Foersch, who was a surgeon at Samarang in 1773) published in the *London Magazine*, December 1783, and popularized by Erasmus Darwin in "Loves of the Plants" (*Botanic Garden*, pt. ii.). The tree was said to destroy all animal life within a radius of 15 miles or more. The poison was fetched by condemned malefactors, of whom scarcely two out of twenty returned. All this is pure fable, and in good part not even traditional fable, but mere invention.

For a scientific account of the *Antiaris*, see Horsfield's *Plantæ Javanicæ Rariores* (1838-52) and Blume's *Rumphia* (Brussels, 1836), and for the legend Yule, *Anglo-Indian Glossary*, p. 726 sq.

UPPER SIND FRONTIER, a district of British India, forming the northernmost portion of the province of Sind, in the Bombay presidency. It comprises an area of 2139 square miles, and lies between 27° 56' and 28° 27' N. lat. and between 68° and 69° 44' E. long. It is bounded on the N. and W. by the Derajat districts of the Punjab and the territory of Khelat, on the S. by Shikarpur district, and on the E. by the Indus. In the north-east the country is hilly; the remainder consists of a narrow strip of level plain, one half being covered with jungle and subject to inundation, from which it is protected by artificial embankments. The land is watered by canals from the Indus, of which the chief is the Begari (85 miles in length), navigable throughout by large boats, and the Desert Canal, which irrigates the country west of Kashmor. The district contains several thriving timber plantations. The wild animals comprise an occasional tiger and hyænas; wild hogs and jackals abound; foxes are occasionally met

with; and antelopes, hog-deer, and a species of *sambhar* deer are found in the dense jungle tracts adjoining the Indus. The climate is remarkable for its dryness and for its extraordinary variations of temperature. The average annual rainfall at Jacobabad is less than 5 inches. There are numerous roads of all descriptions, and the Frontier Military Railway from Sukkur *via* Jacobabad to Sibi crosses the district.

The census of 1881 returned the population as 124,181 (males 70,166, females 54,015),—Hindus numbering 9894, Mohammedans 109,183, and Christians 230. The chief town is Jacobabad, with a population of 7365. In 1885–86 the cultivated area was estimated at 361,415 acres, of which 137,149 were cropped, and of these again 8163 were cropped more than once. The principal crops are wheat, joar, bajra, rice, barley, mustard-seed, and a little cotton and gram. Salt, lacquered work, leathern jars, embroidered shoes, woollen carpets, and saddle-bags are the principal manufactures. The internal trade is principally in grain, the greater part of which is sent to the Punjab, and the transit trade from Central Asia into Sind crosses the district, bringing wool and woollen goods, fruits, carpets, and horses.

UPSALA, a city of Sweden, the seat of its oldest university and residence of the archbishop of Sweden, is situated on the small river Fyris, 42 miles north of Stockholm. In spite of its position in a vast and fertile plain, Upsala was a rather insignificant little town till the opening of railway communication in 1866. The population, which in 1840 was only 5100, had at the end of 1885 increased to more than 20,000 (with students, scholars, and others, 23,000). The industries of the place are still unimportant, but its trade by sea (navigation being open for six or seven months of the year) and by rail is somewhat livelier. Upsala owes its fame to its university, which was founded in 1477. In 1624 Gustavus Adolphus endowed it with 300 farms, the revenue of which formed its entire income for more than two hundred years. Parliament now contributes nearly the half of its whole revenue (393,300 crowns, or about £21,800, in 1885). The professors numbered 58 in 1887, with 61 "docents" and assistant teachers, and there were 1928 students. The last-named are divided into 13 "nations" (based on the old ecclesiastical division of the country), almost every one of which possesses a house of its own, with a hall, reading-rooms, and library. About £7200 is distributed yearly in "stipendia" or scholarships. The new university house, above the cathedral, on the site of the former archbishop's castle, is in the Renaissance style, and was built in 1879–87. It has a great hall capable of holding 2000 persons, eleven lecture-rooms, &c. The vestibule, lighted from above by three large cupolas, and surrounded by open galleries, is particularly fine. The library building (called *Carolina Rediviva*, in remembrance of the Carolina which formerly existed near the cathedral) was erected in 1819–41. The library, which has a right to a copy of every book printed in Sweden, at present (1887) contains 250,000 volumes and 11,000 MSS., among which is the famous *Codex Argenteus* of Ulfilas's translation of the Gospels. The "Gustavianum," built by order of Gustavus Adolphus for a university house, is now wholly occupied by the zoological institution. The botanical garden (which

formerly belonged to the castle) was presented by Gustavus III. to the university in 1787,—the former garden (in the northern part of the city), where Rudbeck and Linnæus worked, and where the residence of the latter is still to be seen, having been found too small and inconvenient. The medical faculty possesses a hospital and anatomical, chemical, and pathologico-physiological institutions; and about a mile from the town there is a magnificent lunatic asylum. The astronomical and meteorological institutions, as well as those of chemistry and physics, have also special buildings, all of recent date. The Royal Society of Sciences, established in 1710 by Eric Benzelius, the younger, occupies a house of its own, and has a valuable library. Of the buildings the cathedral, founded in the latter part of the 13th century and completed in 1435, is the most remarkable. The material is brick, but the proportions are uncommonly noble and harmonious; the length is 390 feet, and the height inside 88. It has suffered considerably from repeated fires, but since 1886 an extensive restoration has been going on. The castle, on the summit of a long ridge above the town, was founded in 1548 by Gustavus I., but not finished till a century later, when it was often used as a royal residence. It was destroyed by fire in 1702, and for more than forty years remained a ruin. At present only a small part of it is habitable, and that part is chiefly used by the provincial government, and as a residence of the governor. Apart from the cathedral and a few insignificant houses, there are no remains from the mediæval period, the city formerly having consisted almost entirely of wooden houses.

The name of Upsala originally belonged to a place nearly 2 miles to the north of the present city, which is still called Old Upsala. This Upsala, mentioned as early as the 9th century, was famous throughout Scandinavia for its splendid heathen temple, which, gleaming with gold, made it the centre of Svithiod, then divided into a great number of kingdoms; three huge grave mounds or barrows still commemorate old times. In the same place the first cathedral of the bishops of Upsala was also erected (about 1100). On the destruction of this building by fire, the inconvenient situation caused the removal in 1273 of the archiepiscopal see to the present city, then called Ostra Aros,¹ but within a comparatively short time it came to be generally called Upsala. During the Middle Ages the cathedral and the see of the archbishop made Upsala a kind of ecclesiastical capital. There the kings were crowned, after the election had taken place at the Mora stones, 10 miles south-east of Upsala. As early as the 14th century, however, Stockholm became the proper residence of the king. In 1567 Erik XIV. murdered in the castle five of the most eminent men of the kingdom, three of them belonging to the family of Sture. In 1593 was held the great synod which marks the final victory of Protestantism in Sweden; in the same year the university was restored by Charles IX. In the castle Christina, daughter of Gustavus Adolphus, resigned her crown to Charles X. in 1654. In 1702 nearly the whole city, with the castle and the cathedral, was burnt down. Among the teachers of the university who have carried its name beyond the boundaries of their own country, the following (besides Linnæus) deserve to be mentioned:—Olof Rudbeck the elder, the author of the *Atlantica* (1630–1702); Torbern Bergman (1735–1784), the celebrated chemist; and Erik Gustaf Geijer (1783–1847), the historian.

¹ The name first occurs in Snorrio Sturluson in connexion with the events of the year 1018; it signifies "the mouth of the eastern river."

Total number of Articles, 625.

PRINCIPAL CONTENTS.

- TABARI.** M. J. DE GOEJE, Professor of Arabic, University of Leyden.
- TABLES, MATHEMATICAL.** J. W. L. GLAISHER, F.R.S., President, Royal Astronomical Society.
- TABOO.** J. G. FRAZER, M.A., Author of "Totemism."
- TACITUS.** Rev. W. J. BRODRIBB, M.A.
- TAHITI.** Baron ANATOLE VON HÜGEL, Curator of the Museum of Archæology, Cambridge.
- TALBOTS.** JAMES GAIRDNER, Public Record Office, London.
- TALES.** ANDREW LANG, M.A., Author of "Custom and Myth."
- TALLEYRAND.** THOS. SHAW, M.A., LL.B.
- TALLIS.** W. S. ROCKSTRO, Author of "General History of Music."
- TALMUD.** S. M. SCHILLER-SZINESSY, M.A., Ph.D.
- TAMILS.** REINHOLD ROST, Ph.D., LL.D., C.I.E., Librarian, India Office, London.
- TAPACULO.** ALFRED NEWTON, M.A., F.R.S., Professor of Zoology, University of Cambridge.
- TAPE-WORMS.** W. E. HOYLE, M.A., "Challenger" Expedition Office.
- TAPIR.** Prof. W. H. FLOWER, LL.D., F.R.S., Director of Natural History, British Museum.
- TAR.** JAMES PATON, Curator, Corporation Galleries of Art, Glasgow, and Prof. W. DITTMAR, LL.D., F.R.S.
- TARGUM.** Dr. S. M. SCHILLER-SZINESSY.
- TARTARIC ACID.** Prof. W. DITTMAR.
- TASMANIA.** JAMES BONWICK, Author of "The Lost Tasmanian Race."
- TASSIE.** J. M. GRAY, Curator, Scottish National Portrait Gallery.
- TASSO.** J. A. SYMONDS, M.A., Author of "The Renaissance in Italy."
- TASTE.** J. G. M'KENDRICK, M.D., LL.D., F.R.S., Professor of Institutes of Medicine, University of Glasgow.
- TATIAN.** ADOLF HARNACK, D.D., Professor of Church History, University of Marburg.
- TAXATION.** J. SHIELD NICHOLSON, M.A., D.Sc., Professor of Political Economy, University of Edinburgh.
- TAXIDERMY.** MONTAGUE BROWNE, Author of "Practical Taxidermy."
- TAYLOR, SIR HENRY.** RICHARD GARNETT, LL.D.
- TAYLOR, JEREMY.** Rev. MARCUS DODS, D.D.
- TEA.** JAMES PATON.
- TEAK.** Sir DIETRICH BRANDIS, K.C.I.E., Ph.D., F.R.S.
- TECHNICAL EDUCATION.** Sir PHILIP MAGNUS.
- TELEGRAPH.** THOMAS GRAY, B.Sc., F.R.S.E.
- TELEMETER.** Major ARTHUR W. WHITE, R.A., School of Gunnery, Aldershot.
- TELEPHONE.** THOMAS GRAY.
- TELESCOPE.** DAVID GILL, LL.D., Astronomer Royal, Cape of Good Hope.
- TELL.** Rev. W. A. B. COOLIDGE, M.A., Editor of "The Alpine Journal."
- TEMPERA.** J. HENRY MIDDLETON, M.A., Slade Professor of Fine Art, University of Cambridge.
- TEMPLARS.** T. A. ARCHER.
- TEMPLE.** W. ROBERTSON SMITH, LL.D.
- TEMPLE, SIR WILLIAM.** G. W. PROTHERO, M.A., Lecturer in History, King's College, Cambridge.
- TENIERS.** HENRI HYMANS, Conservateur, Bibliothèque Royale, Brussels.
- TENNESSEE.** DANIEL F. WRIGHT, M.D., Clarksville, Tenn.
- TENNIS.** JULIAN MARSHALL, Author of "Annals of Tennis."
- TEREDO.** J. T. CUNNINGHAM, B.A., Fellow of University College, Oxford.
- TERENCE.** W. Y. SELLAR, LL.D., Professor of Humanity, University of Edinburgh.
- TERRA COTTA.** Prof. J. H. MIDDLETON.
- TERTULLIAN.** Prof. A. HARNACK.
- TEXAS.** ROBERT T. HILL, Author of "Geological Knowledge of Texas" (U.S. Geological Survey).
- TEXTILES.** Prof. J. H. MIDDLETON.
- THACKERAY.** WALTER H. POLLOCK.
- THALES.** Prof. G. J. ALLMAN, LL.D., F.R.S., Galway, and HENRY JACKSON, Litt.D., Trinity College, Cambridge.
- THEATRE—**
- CONSTRUCTION. Prof. J. H. MIDDLETON.
- LAW. JAMES WILLIAMS, B.C.L., Barrister-at-Law.
- THERBES.** A. W. VERRALL, M.A., Lecturer in Classics, Trinity College, Cambridge.
- THEFT.** JAMES WILLIAMS.
- THEISM.** Rev. ROBERT FLINT, D.D., LL.D., Professor of Divinity, University of Edinburgh.
- THEMISTOCLES.** Rev. W. J. BRODRIBB.
- THÉNARD.** A. CRUM BROWN, M.D., LL.D., F.R.S., Professor of Chemistry, University of Edinburgh.
- THEOCRITUS.** ANDREW LANG.
- THEODORA.** JAMES BRYCE, D.C.L., M.P., Regius Professor of Civil Law, University of Oxford.
- THEODORIC.** THOMAS HODGKIN, D.C.L., LL.D., Author of "Italy and her Invaders."
- THEODOSIUS.** T. A. ARCHER.
- THEOLOGY.** Prof. R. FLINT.
- THEOSOPHY.** ANDREW SETH, M.A., Professor of Logic, University of St Andrews.
- THERESA.** Prof. A. SETH.
- THERMODYNAMICS.** P. G. TAIT, M.A., Professor of Natural Philosophy, University of Edinburgh.
- THERMOMETER.** H. R. MILL, D.Sc.
- THESEUS.** J. G. FRAZER.
- THESSALONIANS, EPISTLES TO THE.** E. SCHÜTZER, Professor of New Testament Theology, Giessen.
- THESSALY.** Rev. H. F. TOZER, M.A., Author of "Turkish Armenia and Eastern Asia Minor."
- THIBAUT.** JOHN MACDONELL, M.A., Author of "The Land Question."

THIERS. GEORGE SAINTSBURY, M.A., Author of "Short History of French Literature."
THIRLWALL. RICHARD GARNETT, LL.D.
THOMPSON, SIR BENJAMIN. FRED. DRUMMOND.
THOMSON, JAMES. WM. MINTO, M.A., Professor of English Language, University of Aberdeen.
THOREAU. WILLIAM SHARP, Author of "Life of Shelley."
THOUSAND AND ONE NIGHTS. Prof. M. J. DE GOEJE.
THRACE. Rev. H. F. TOZER.
THROAT DISEASES. J. O. AFFLECK, M.D.
THRUSH. Prof. A. NEWTON.
THUCYDIDES. R. O. JEBB, LL.D., Professor of Greek, University of Glasgow.
THUGS. REINHOLD ROST, LL.D., C.I.E.
THULE. Sir EDWARD H. BUNBURY, Bart., Author of "History of Ancient Geography."
THUNDERSTORM. Prof. P. G. TAIT.
THURLOW. A. WOOD RENTON, LL.B.
TIBERIUS. J. S. REID, Litt.D., Fellow and Tutor of Caius College, Cambridge.
TIBET. General J. T. WALKER, R.E., C.B., F.R.S., and A. TERBIEN DE LACOUPERIE, Professor of Indo-Chinese Philology, University College, London.
TIBULLUS. J. P. POSTGATE, Litt.D., Professor of Comparative Philology, University College, London.
TIDES. G. H. DARWIN, M.A., F.R.S., Plumian Professor of Astronomy and Experimental Philosophy, University of Cambridge.
TIECK. RICHARD GARNETT, LL.D.
TIERRA DEL FUEGO. A. H. KEANE, B.A., Professor of Hindustani, University College, London.
TIGER. Prof. W. H. FLOWER.
TILES. Prof. J. H. MIDDLETON.
TIME. J. L. E. DREYER, Ph.D., Astronomer, Armagh Observatory.
TIMUR. Maj.-Gen. Sir FREDERICK J. GOLDSMID, K.O.S.I., C.B.
TIN. Prof. W. DITTMAR.
TINAMOU. Prof. A. NEWTON.
TIBYNS. Prof. J. H. MIDDLETON.
TITHES. W. ROBERTSON SMITH, LL.D., and JAMES WILLIAMS, B.C.L.
TITIAN. W. M. ROSSETTI.
TITLES OF HONOUR. FREDERICK DRUMMOND.
TOBACCO. JAMES PATON and Prof. W. DITTMAR.
TOBIT. W. ROBERTSON SMITH, LL.D.
TOBOLSK. P. A. KROPOTKINE.
TOKIO. R. S. LANE, Japanese Legation, London.
TOMSK. P. A. KROPOTKINE.
TONG-KING. R. K. DOUGLAS, Professor of Chinese, King's College, London.
TONNAGE. W. MOORE, Principal Surveyor of Tonnage, Board of Trade, London.
TOOKE. W. P. COURTNEY.
TORONTO. DANIEL WILSON, LL.D., President, University College, Toronto.
TORPEDO. Commander EDWIN J. P. GALLWEY, H.M.S. "Polyphemus."
TORT. FREDERICK POLLOCK, LL.D., Corpus Professor of Jurisprudence, University of Oxford.
TORTOISE. ALBERT GÜNTHER, M.D., Ph.D., F.R.S., Author of "The Study of Fishes."
TORTURE. JAMES WILLIAMS.
TOTEMISM. J. G. FRAZER.
TOUCAN. Prof. A. NEWTON.
TOUCH. Prof. J. G. M'KENDBICK.

TOULOUSE. GASTON MEISSAS and T. A. ARCHER.
TOURACO. Prof. A. NEWTON.
TOURNEUR. A. C. SWINBURNE.
TRACTION. J. A. EWING, B.Sc., F.R.S., Professor of Engineering, University College, Dundee.
TRADE UNIONS. FRED. DRUMMOND.
TRAJAN. J. S. REID, Litt.D.
TRAMWAY. THOMAS CODRINGTON, C.E., Engineer & Inspector, Local Government Board, Whitehall.
TRANSCAUCASIA. P. A. KROPOTKINE.
TRANSIT CIRCLE. J. L. E. DREYER, Ph.D.
TRANSVAAL. Prof. A. H. KEANE.
TRANSVERSE FLUTE. VICTOR MAHILLON, Conservatoire Royal de Musique, Brussels.
TRAPPISTS. Rev. R. F. LITLEDALE, D.C.L., LL.D.
TREASON. JAMES WILLIAMS.
TREATIES. THOMAS E. HOLLAND, D.C.L., Chichele Professor of International Law and Diplomacy, University of Oxford.
TREMATODA. W. E. HOYLE.
TRENCH. RICHARD GARNETT, LL.D.
TRENDELENBURG. Prof. A. SETH.
TRENT, COUNCIL OF. Rev. Dr. LITLEDALE.
TRIBUNE. J. S. REID, Litt.D.
TRICYCLE. O. V. BUYS, Science School, South Kensington.
TRIGONOMETRY. E. W. HOBSON, M.A., Lecturer in Mathematics, Christ's College, Cambridge.
TRIPOLI. A. M. BROADLEY, Author of "Tunis, Past and Present."
TROAD. Prof. R. C. JEBB.
TROLLOPE, ANTHONY. GEORGE SAINTSBURY.
TROMBONE. VICTOR MAHILLON.
TRUMPET. VICTOR MAHILLON.
TRUST. JAMES WILLIAMS.
TUNICATA. W. A. HERDMAN, D.Sc., Professor of Natural History, University College, Liverpool.
TUNNELLING. BENJAMIN BAKER, C.E.
TURBOT. J. K. INGRAM, LL.D.
TURKESTAN. P. A. KROPOTKINE.
TURKEY—
HISTORY AND LITERATURE. E. J. W. GIBB, Author of "Ottoman Poems," and C. A. FYFFE, M.A., Author of "History of Modern Europe."
GEOGRAPHY AND STATISTICS. Prof. A. H. KEANE.
TURKS. Prof. M. TH. HOUTSMA, University of Leyden.
TURNER. GEORGE REID, R.S.A.
TYPHUS, TYPHOID, AND RELAPSING FEVERS. J. O. AFFLECK, M.D.
TYPOGRAPHY—
HISTORY. J. H. HESSELS, M.A.
PRACTICAL. JOHN SOUTHWARD.
TYROL. A. J. BUTLER, M.A.
ULFILAS. Rev. C. ANDERSON SCOTT, B.A.
UMBRIA. WILLIAM RIDGEWAY, M.A., Professor of Greek, Queen's College, Cork.
UNITARIANISM. Rev. J. F. SMITH.
UNITED STATES—
HISTORY. ALEXANDER JOHNSTON, Professor of Jurisprudence and Political Economy, Princeton College, N.J.
GEOGRAPHY AND STATISTICS. Prof. J. D. WHITNEY, Harvard College, Cambridge, Mass., and General F. A. WALKER, Superintendent, United States Tenth Census, Washington, D.C.
UNIVERSITIES. J. BASS MULLINGER, M.A., Librarian, St John's College, Cambridge.
